## Abstract

We show that  $\mathbf{AC}^0$  circuits on  $n$  variables with depth  $d$  and size  $m$  have at most  $2^{-\Omega(k/\log^{d-1} m)}$  of their Fourier mass at level  $k$  or above. Our proof builds on a previous result by Håstad (SICOMP, 2014) who proved this bound for the special case  $k = n$ . Our result improves the seminal result of Linial, Mansour and Nisan (JACM, 1993) and is tight up to the constants hidden in the  $\Omega$  notation.

As an application, we improve Braverman's celebrated result (JACM, 2010). Braverman showed that any  $r(m, d, \varepsilon)$ -wise independent distribution  $\varepsilon$ -fools  $\mathbf{AC}^0$  circuits of size  $m$  and depth  $d$ , for

$$r(m, d, \varepsilon) = O(\log(m/\varepsilon))^{2d^2+7d+3}.$$

Our improved bounds on the Fourier tails of  $\mathbf{AC}^0$  circuits allows us to improve this estimate to

$$r(m, d, \varepsilon) = O(\log(m/\varepsilon))^{3d+3}.$$

In contrast, an example by Mansour (appearing in Luby and Velickovic's paper – Algorithmica, 1996) shows that there is a  $\log^{d-1}(m) \cdot \log(1/\varepsilon)$ -wise independent distribution that does not  $\varepsilon$ -fool  $\mathbf{AC}^0$  circuits of size  $m$  and depth  $d$ . Hence, our result is tight up to the factor 3 in the exponent.

## 1 Introduction

In this paper we discuss Boolean circuits in which every gate computes an unbounded fan-in OR or AND function of its inputs, and every leaf is marked with a literal from  $x_1, \dots, x_n, \neg x_1, \dots, \neg x_n$ . The number of gates in the circuit is called the **circuit size** and is denoted by  $m$ . The longest path in the circuit is called the **circuit depth** and is denoted by  $d$ .  $\mathbf{AC}^0$  is the class of functions that can be realized by Boolean circuits of constant depth and polynomial size. (We also call Boolean circuits of polynomial size and constant depth  $\mathbf{AC}^0$  circuits).

The study of bounded depth circuits flourished in the 1980s, culminating in the tight  $\exp(\Omega(n^{1/(d-1)}))$  size lower bound for Boolean circuits of depth  $d$  computing the parity function [2, 11, 36, 14].<sup>1</sup> The main idea behind this lower bound was the following – Boolean

<sup>1</sup> Lower bounds for the **DNF**-size of the parity function were known long before [24].

circuits with size  $m$  and depth  $d$  become constant with high probability under random restrictions keeping each variable alive with probability  $p = 1/O(\log m)^{d-1}$ . In contrast, the parity function does not become a constant with probability at least 0.5 as long as  $pn \geq 1$ . Since the restricted circuit should compute the restricted function, we reach a contradiction if  $m = \exp(o(n^{1/(d-1)}))$ . The main idea is carried through a sequence of  $d - 1$  steps, where in each step the circuit depth is decreased by one with high probability, by applying Håstad's switching lemma [14].

In their seminal paper, Linial, Mansour, and Nisan [22] showed that  $\mathbf{AC}^0$  circuits can be learned in quasipolynomial time,  $n^{O(\log^d n)}$ , using random samples, under the uniform distribution. They combined Håstad's switching lemma with Fourier analysis, to show that  $\mathbf{AC}^0$  circuits may be well approximated (in  $L_2$  norm) by low degree polynomials, namely polynomials of degree  $O(\log^d n)$ . Boppana [6] improved their bound on the degree to  $O(\log^{d-1} n)$ , which is optimal for constant error. The existence of an approximating low degree polynomial implies a learning algorithm for  $\mathbf{AC}^0$  circuits, using random examples. For polynomial size  $\mathbf{DNFs}$  (depth 2 circuits), Mansour [25] showed that only  $n^{O(\log \log n)}$  out of the  $\binom{n}{\leq O(\log n)}$  monomials are needed to approximate the  $\mathbf{DNF}$ , and achieved a  $n^{O(\log \log n)}$  time learning algorithm for  $\mathbf{DNFs}$ , using membership queries, via the Goldreich-Levin [12], Kushilevitz-Mansour [21] method.

The main technical result in [22] was a bound on the Fourier tails of Boolean circuits. Namely, for any circuit  $f$  of size  $m$  and depth  $d$ ,

$$\sum_{S \subseteq [n]: |S| \geq k} \hat{f}(S)^2 \leq m \cdot 2^{-\Omega(k^{1/d})},$$

where the LHS is called the Fourier tail of  $f$  at level  $k$ . This was later improved by Håstad [15] to

$$\sum_{S \subseteq [n]: |S| \geq k} \hat{f}(S)^2 \leq \max\{2^{-\Omega((k/\log m)^{1/(d-1)})}, 2^{-\Omega(k/\log^{d-1}(m))}\},$$

which is tight for  $k \leq O(\log^d(m))$ , however not for larger values of  $k$ . Recently, Håstad [16] and Impagliazzo, Matthews, and Paturi [18] showed that any Boolean circuit  $f$  agrees with parity on at most a  $1/2 + 2^{-n/O(\log m)^{d-1}}$  fraction of the inputs. In other words, they showed that  $|\hat{f}([n])| \leq 2^{-n/O(\log m)^{d-1}}$ .

### 1.1 Our Results

Based on the main lemma of [16], we extend the results of [16, 18] for all  $k \in [0, n]$  and show the following.

► **Theorem 1 (Main Theorem).** *Let  $f$  be an Boolean circuit with depth  $d$  and size  $m$ . Then,*

$$\sum_{S: |S| \geq k} \hat{f}(S)^2 \leq 2 \cdot 2^{-k/O(\log m)^{d-1}}.$$

A few things to note first. Increasing  $k$  from 0 to  $n$ , the first time that Theorem 1 is meaningful is at  $k = \Theta(\log^{d-1}(m))$ , which is only marginally better than in [22] and exactly the same as in [6, 15]. Nonetheless, for larger values, our bound decreases much faster, and in particular for  $m = \text{poly}(n)$  we get a  $2^{-n/\text{poly} \log(n)}$  tail at level  $k = \Omega(n)$  as opposed to a  $2^{-\Omega((n/\log n)^{1/(d-1)})}$  tail by [15]. In addition, while [16] and [18] give bounds on an individual coefficient,  $|\hat{f}(S)|$ , we give bounds on the sum of  $\exp(\Omega(n))$  many squares of coefficients (e.g., for  $k = n/2$ ).

We point out that the results of [16], [18], and ours are quite surprising, considering the fact that most proofs for Boolean circuits follow by induction on the depth  $d$ ; performing  $d - 1$  consecutive steps of Håstad's switching lemma. Our main theorem is equivalent to saying that degree  $O(\log^{d-1}(m) \cdot \log(1/\varepsilon))$  polynomials  $\varepsilon$ -approximates Boolean circuits of size  $m$  and depth  $d$ , as opposed to degree  $O(\log^d(m/\varepsilon))$  polynomials by [22]. It seems at first glance that one *must* pay a factor of  $\log(m/\varepsilon)$  for each step in the induction to ensure error at most  $\varepsilon$ , thus resulting in degree at least  $\log^{d-1}(m/\varepsilon)$ . However, Håstad and Impagliazzo et al. managed to avoid that. Håstad performs random restrictions keeping each variable alive with probability  $p = 1/O(\log m)$  that does not depend on  $\varepsilon$ . This only guarantee that the switching succeeds with probability  $1 - 1/\text{poly}(m)$ , as opposed to probability of  $1 - \varepsilon/m$  in the original proof of [22]. However, in the cases where the switching “fails”, Håstad fixes  $D$  additional variables using a decision tree of depth  $D$ . Under these additional fixings, the probability that the switching fails reduces to  $m \cdot 2^{-D}$ . We show that the parameters  $p$  and  $D$  translate into a **multiplicative** term of  $1/p$  and an **additive** term of  $D$  in the degree, correspondingly. Choosing  $D$  to be roughly  $\log(m/\varepsilon)$  and applying induction gives the desired dependency on  $m$  and  $\varepsilon$ .

Theorem 1 shows that the Fourier tail above level  $k$  decreases exponentially fast in  $k$ . In Section 5, we show that such behavior is related to three other properties of concentration. We establish many connections between these four properties, and show that three of them are essentially equivalent. We think that these connections are of independent interest.<sup>2</sup> As a result of these connections we establish the following theorem.

► **Theorem 2.** *Let  $f$  be an Boolean circuit with depth  $d$  and size  $m$ . Then,*

1. *For all  $k, p$ , if  $\rho$  is a  $p$ -random restriction, then  $\Pr_{\rho}[\deg(f|_{\rho}) \geq k] \leq O(p \cdot \log^{d-1}(m))^k$ .*
2. *For all  $k$ ,*

$$\sum_{S:|S|=k} |\hat{f}(S)| \leq O(\log^{d-1}(m))^k. \quad (1)$$

3.  *$f$  is  $\varepsilon$ -concentrated on at most  $2^{O(\log \log(m) \cdot \log^{d-1}(m) \cdot \log(1/\varepsilon))}$  Fourier coefficients.*

In Section 6, we show that Equation (1) gives new proofs for the following known results:

- Correlation bounds for the Majority function. If  $f$  is a size  $m$  depth  $d$  circuit, then  $\Pr[f(x) = \text{MAJ}(x)] \leq \frac{1}{2} + \frac{O(\log^{d-1}(m))}{\sqrt{n}}$ . Our result holds for  $\log^{d-1}(m) = O((n/\log n)^{1/3})$ , which is an artifact of the proof. This result was originally proved by Smolensky [32] (see also [10]) and by O'Donnell and Wimmer [28], for the entire range of parameters.
- Boolean circuits cannot distinguish between fair coins and coins with bias at most  $\frac{1}{O(\log^{d-1}(m))}$ . This result was previously proved by Cohen, Ganor and Raz [8], improving the results of Aaronson [1], and Shaltiel and Viola [31].

## 1.2 Applications to Pseudorandomness and Learning

Since the result of [22] had many applications, our main theorem improves some of them as well.

<sup>2</sup> In fact, some of these connections have been already used in the context of de Morgan formulae [33].

**$k$ -wise independence fools bounded-depth circuits.** The most significant improvement is to the work of Braverman [7] who proved a longstanding conjecture, showing that poly-logarithmic independent distributions fool  $\mathbf{AC}^0$  circuits. To be more precise, Braverman showed that any  $k$ -wise independent distribution, where  $k = O(\log(m/\varepsilon))^{2d^2+7d+3}$ ,  $\varepsilon$ -fools circuits of size  $m$  and depth  $d$ . In addition, it was long known [23] that  $k$  must be larger than  $\Omega(\log^{d-1}(m) \cdot \log(1/\varepsilon))$ ; otherwise, there is a  $k$ -wise independent distribution that is  $\varepsilon$ -distinguishable from the uniform distribution by a depth  $d$ , size  $m$  circuit. Our theorem improves Braverman’s bounds to  $k = O(\log(m/\varepsilon))^{3d+3}$ , answering an open question posed by Braverman on the affirmative. In particular, our result is non-trivial for polynomial size circuits of depth  $d \leq 0.3 \log(n) / \log \log(n)$ . Since  $\mathbf{NC}^1$  circuits can be computed by Boolean circuits of depth  $O(\log(n) / \log \log(n))$  and polynomial size, constructing a non trivial PRG for all  $d = O(\log(n) / \log \log(n))$  is a major open challenge. While the dependence of  $k$  on  $m$  and  $d$  is close to optimal, we conjecture that the dependence on  $\varepsilon$  could be much better.<sup>3</sup>

► **Conjecture 3.** *Any  $k$ -wise independence  $\varepsilon$ -fools circuits of size  $m$  and depth  $d$ , for*

$$k = (\log m)^{O(d)} \cdot \log(1/\varepsilon).$$

**$k$ -wise independence fools DNFs.** We improve in Section 4.2 the earlier result of Bazzi [4], who showed that  $O(\log^2(m/\varepsilon))$ -wise independence  $\varepsilon$ -fools **DNFs** of size  $m$ . We improve the dependence on  $\varepsilon$  and get that  $O(\log(m) \cdot \log(m/\varepsilon))$ -wise independence suffices. Note that by [23] this is optimal for  $\varepsilon \leq 1/m^{\Omega(1)}$ . The range  $\varepsilon \geq 1/m^{o(1)}$  is still not tightly understood.

**PRGs for  $\mathbf{AC}^0$  and DNFs.** We improve the results of De et al. [9] (see Appendix C) and of Trevisan and Xue [35] (see Appendix D) that give the best known PRGs for **DNFs** and  $\mathbf{AC}^0$  circuits respectively. In the PRG of De et al., we improve the dependency of the seed-length in  $\varepsilon$ , as seen in Figure 1. Since Trevisan and Xue used De et al.’s generator as a black-box in their construction, we also improve the seed length of their PRG for  $\mathbf{AC}^0$  circuits. We observe two more improvements in the Trevisan-Xue generator to reduce the seed-length to  $\tilde{O}(\log^{d+1}(m/\varepsilon) \cdot \log(n))$ . This seed-length comes closer to the barrier  $O(\log^d(m/\varepsilon))$  noted by [35].

**Sparse polynomial approximations of Boolean circuits.** Theorem 2 shows that any Boolean circuit  $f$  of size  $m$  and depth  $d$  can be  $\varepsilon$ -approximated in  $L_2$  by a polynomial  $p(x)$  of sparsity  $(\log m)^{O(\log^{d-1}(m) \cdot \log(1/\varepsilon))}$ , improving the results of [22] and [25]. As the inner product on  $k = \log^{d-1} m$  variables can be realized by a size  $\text{poly}(m)$  depth  $d$  circuit, and requires at least  $\Omega(2^k)$  coefficients in order to  $\Omega(1)$  approximate in  $L_2$ , one cannot achieve sparsity  $2^{o(\log^{d-1} m)}$ .

A table summarizing all of the improvements mentioned above is presented in Figure 1.

### 1.3 Organization

In Section 2, we lay out some preliminary definitions and results that will be used in the rest of the paper. In Section 3, we prove our main theorem, i.e. Theorem 1. In Section 4, we improve Braverman’s and Bazzi’s results in the field of pseudorandomness. In Section 5, we prove Theorem 2, by relating different notions of Fourier concentration. Then, in section 6, we use Theorem 2 to deduce simpler proofs for two known results: the inapproximability of

---

<sup>3</sup> We have learned that subsequent to this work, Harsha and Srinivasan [13] proved this conjecture.

■ **Figure 1** Summary of Applications.

the Majority function by bounded-depth circuits, and the indistinguishability of biased-coins from uniform coins by bounded-depth circuits. In Section 7, we give a self-contained new proof of the main lemma in the work of Håstad [16], that plays a crucial role in the proof of Theorem 1. This serves two purposes. First, it makes the main result in our paper self-contained. Second, in our opinion, it gives a simpler proof of Håstad’s main lemma ([16]).

In the appendices, we revisit the works of Braverman [7] (Appendix B), De et al. [9] (Appendix C), and Trevisan and Xue [35] (Appendix D) in the field of pseudorandomness. We show how our main results (Theorem 1 and Theorem 2) improve these results. Furthermore, we reduce the seed-length of the PRG of [35] even further using several other observations.

## 2 Preliminaries

We denote by  $[n] = \{1, \dots, n\}$ . We denote by  $\log$  and  $\ln$  the logarithms in bases 2 and  $e$ , respectively. For  $f : \{-1, 1\} \rightarrow \mathbb{R}$  we denote by  $\|f\|_p = (\mathbf{E}_{x \in \{-1, 1\}^n} [|f(x)|^p])^{1/p}$ .

### 2.1 Restrictions

► **Definition 4** (Restriction). Let  $f : \{0, 1\}^n \rightarrow \{0, 1\}$  be a Boolean function. A restriction  $\rho$  is a vector of length  $n$  of elements from  $\{0, 1, *\}$ . We denote by  $f|_\rho : \{0, 1\}^n \rightarrow \{0, 1\}$  the function  $f$  restricted according to  $\rho$ , defined by

$$f|_\rho(x) = f(y), \quad \text{where} \quad y_i = \begin{cases} x_i, & \rho_i = * \\ \rho_i, & \text{otherwise} \end{cases}.$$

We say that the variable  $x_i$  is fixed if  $\rho_i \in \{0, 1\}$ , and that  $x_i$  is unassigned (or alive) if  $\rho_i = *$ .

## 15:6 Tight Bounds on the Fourier Spectrum of $\text{AC}^0$

Note that the function  $f|_\rho$  is defined as a function with  $n$  variables, although it depends only on the non-fixed variables. When fixing only one bit to a constant, we may denote the restricted function by  $f|_{x_i=b}$ .

► **Definition 5** ( $p$ -Random Restriction). A  $p$ -random restriction is a restriction as in Definition 4 that is sampled in the following way. For every  $i \in [n]$ , independently, with probability  $p$  set  $\rho_i = *$  and with probability  $\frac{1-p}{2}$  set  $\rho_i$  to be  $-1$  and  $1$ , respectively. We denote this distribution of restrictions by  $\mathcal{R}_p$ .

### 2.2 Fourier Analysis of Boolean Functions

Any function  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$  has a unique Fourier representation:

$$f(x) = \sum_{S \subseteq [n]} \hat{f}(S) \cdot \prod_{i \in S} x_i,$$

where the coefficients  $\hat{f}(S) \in \mathbb{R}$  are given by  $\hat{f}(S) = \mathbf{E}_x[f(x) \cdot \prod_{i \in S} x_i]$ . Parseval's identity states that  $\sum_S \hat{f}(S)^2 = \mathbf{E}_x[f(x)^2] = \|f\|_2^2$ , and in the case that  $f$  is Boolean (i.e.,  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$ ), all are equal to 1. The Fourier representation is the unique multilinear polynomial which agrees with  $f$  on  $\{-1, 1\}^n$ . We denote by  $\deg(f)$  the degree of this polynomial, which also equals  $\max\{|S| : \hat{f}(S) \neq 0\}$ . We denote by

$$\mathbf{W}^k[f] \triangleq \sum_{S \subseteq [n], |S|=k} \hat{f}(S)^2$$

the Fourier weight at level  $k$  of  $f$ . Similarly, we denote  $\mathbf{W}^{\geq k}[f] \triangleq \sum_{S \subseteq [n], |S| \geq k} \hat{f}(S)^2$ . The truncated Fourier expansion of degree  $k$  of  $f$  is simply  $f^{\leq k}(x) = \sum_{|S| \leq k} \hat{f}(S) \prod_{i \in S} x_i$ . By Parseval,  $\|f - f^{\leq k}\|_2^2 = \mathbf{W}^{\geq k+1}[f]$ . The following fact relates the Fourier coefficients of  $f$  and  $f|_\rho$ , where  $\rho$  is a  $p$ -random restriction.<sup>4</sup>

► **Fact 6** (Proposition 4.17, [27]). Let  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$ ,  $S \subseteq [n]$ , and  $p > 0$ . Then,

$$\mathbf{E}_{\rho \sim \mathcal{R}_p} [\widehat{f|_\rho}(S)] = \hat{f}(S) p^{|S|}$$

and

$$\mathbf{E}_{\rho \sim \mathcal{R}_p} [\widehat{f|_\rho}(S)^2] = \sum_{U \subseteq [n]} \hat{f}(U)^2 \cdot \mathbf{Pr}_{\rho \sim \mathcal{R}_p} [\{i \in U : \rho(i) = *\} = S].$$

Summing the last equation over all sets  $S$  of size  $d$  gives the following corollary.

► **Fact 7**. Denote by  $\text{Bin}(k, p)$  a binomial random variable with parameters  $k$  and  $p$ . Then,

$$\mathbf{E}_{\rho \sim \mathcal{R}_p} [\mathbf{W}^d[f|_\rho]] = \sum_{k=d}^n \mathbf{W}^k[f] \cdot \mathbf{Pr}[\text{Bin}(k, p) = d].$$

► **Definition 8** (Fourier Sparsity, Spectral Norm). We define the sparsity of  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$  as  $\text{sparsity}(f) \triangleq |\{S : \hat{f}(S) \neq 0\}|$ ; the spectral norm of  $f$  as  $L_1(f) \triangleq \sum_S |\hat{f}(S)|$ ; and the spectral norm of the  $k$ -th level of  $f$  as  $L_{1,k}(f) \triangleq \sum_{S:|S|=k} |\hat{f}(S)|$ .

<sup>4</sup> Note that  $\widehat{f|_\rho}(S) = 0$  if  $\rho$  fixes one of the variables in  $S$ .

We state the following known fact regarding the Fourier sparsity, spectral norm and granularity of low degree Boolean functions.

► **Fact 9** (Ex. 1.11, [27]). *Let  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$  with  $\deg(f) = d$ . Then:*

1.  $\forall S : |\hat{f}(S)| = k_S \cdot 2^{-d}$  where  $k_S \in \mathbb{Z}$ .
2.  $\text{sparsity}(f) \leq 2^{2d}$ .
3.  $L_1(f) \leq 2^d$ .

### 3 Exponentially Small Fourier Tails for Bounded Depth Circuits

We generalize the proof of Håstad ([16]), who showed that the correlation between the parity function and any Boolean circuit of depth  $d$  and size  $m$  is at most  $2^{-\Omega(n/\log^{d-1}(m))}$ . This bound is tight up to the constants in the exponent, as shown by an example in [16], and improves upon previous bounds from [22, 15].

We will use two simple lemmata which explain the behavior of Fourier tails with respect to random restrictions, and arbitrary restrictions.

► **Lemma 10** ([22]). *For any  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$ ,  $k \in \mathbb{N} \cup \{0\}$  and  $p \in [0, 1]$ ,*

$$\mathbf{W}^{\geq k}[f] \leq 2 \cdot \mathbf{E}_{\rho \sim \mathcal{R}_p} \left[ \mathbf{W}^{\geq \lfloor kp \rfloor}[f|_{\rho}] \right].$$

**Proof.** Let  $k \in \mathbb{N} \cup \{0\}$  and  $p \in [0, 1]$ . We have

$$\begin{aligned} \mathbf{E}_{\rho \sim \mathcal{R}_p} \left[ \mathbf{W}^{\geq \lfloor kp \rfloor}[f|_{\rho}] \right] &= \sum_{\ell \geq \lfloor kp \rfloor} \mathbf{W}^{\ell}[f] \cdot \Pr[\text{Bin}(\ell, p) \geq \lfloor kp \rfloor] && \text{(Fact 7)} \\ &\geq \sum_{\ell \geq k} \mathbf{W}^{\ell}[f] \cdot \Pr[\text{Bin}(\ell, p) \geq \lfloor kp \rfloor] \\ &\geq \sum_{\ell \geq k} \mathbf{W}^{\ell}[f] \cdot 1/2 && (\text{median}(\text{Bin}(\ell, p)) \geq \lfloor \ell p \rfloor \geq \lfloor kp \rfloor, [19]) \\ &= 1/2 \cdot \mathbf{W}^{\geq k}[f]. && \blacktriangleleft \end{aligned}$$

The second lemma, taken from [17], states that if, for some bit, we have Fourier tail bounds for both restrictions fixing that bit to either +1 or -1, then we have Fourier tail bounds for the unrestricted function.

► **Lemma 11** ([17]). *Let  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$  and  $i \in [n]$ . Then,*

$$\mathbf{W}^{\geq k}[f] \leq \frac{1}{2} \cdot \mathbf{W}^{\geq k-1}[f|_{x_i=-1}] + \frac{1}{2} \cdot \mathbf{W}^{\geq k-1}[f|_{x_i=1}].$$

In order to generalize the last lemma, we introduce the following definition, which is very similar to the definition of a decision tree, except we are not making any decision!

► **Definition 12** (Restriction Tree). A restriction tree is a rooted directed binary tree such that each internal node is labeled by a variable from  $x_1, \dots, x_n$  and has two outgoing edges: one marked with 1 and one marked with -1. The leaves of the tree are not labeled. Each leaf in the tree,  $\ell$ , corresponds to a restriction  $\tau_{\ell}$  on the variables  $x_1, \dots, x_n$  in the most natural way: we fix the variables along the path from the root to the leaf  $\ell$  according to the values on the path edges.

Using induction, Lemma 11 implies (informally) that if, for some restriction tree, we have Fourier tail bounds for restrictions corresponding to all root-leaf paths in the tree, then we have Fourier tail bounds for the unrestricted function as well. The exact statement follows.

► **Lemma 13.** *Let  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$  be a function, and let  $T$  be a restriction tree of depth  $\leq D$  such that for any leaf  $\ell$ , under the corresponding restriction  $\mathbf{W}^{\geq k}[f|_{\tau_\ell}] \leq \varepsilon$ . Then,  $\mathbf{W}^{\geq k+D}[f] \leq \varepsilon$ .*

**Proof.** Apply induction on the depth of the restriction tree. For depth 0 this obviously holds. For depth  $D$ , consider both subtrees that are rooted by the children of the original root. If the root queries  $x_i$ , these are restriction trees for  $\{x : x_i = 1\}$  and  $\{x : x_i = -1\}$ , and we may apply the induction hypothesis on each subtree to get  $\mathbf{W}^{\geq k+(D-1)}[f|_{x_i=1}] \leq \varepsilon$  and  $\mathbf{W}^{\geq k+(D-1)}[f|_{x_i=-1}] \leq \varepsilon$ . Finally, applying Lemma 11 gives  $\mathbf{W}^{\geq k+D}[f] \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon$ . ◀

Our proof relies on the main lemma in Håstad's work [16]. We begin with a definition from [16] and the statement of his main lemma.

► **Definition 14** (Common Partial Decision Tree). A set of functions  $(g_i)_{i=1}^m$  has a common  $s$ -partial decision tree of depth  $D$ , if there is a restriction tree of depth  $D$  such that at each leaf  $\ell$  of this restriction tree, each function  $g_i$ , restricted by  $\tau_\ell$ , is computable by an ordinary decision tree of depth  $s$ .

► **Lemma 15** ([16], Lemma 3.8). *Let  $(f_i)_{i=1}^m$  be a collection of depth-2 circuits, each of bottom fan-in  $t$ . Let  $\rho$  be a random restriction from  $\mathcal{R}_p$ . Then the probability that  $(f_i|_\rho)_{i=1}^m$  is not computable by a common  $\log(2m)$ -partial decision tree of depth  $D$  is at most  $m \cdot (24pt)^D$ .*

In Appendix 7 we give a new proof for Lemma 15 (with constant 49 instead of 24) following the proof approach of [29], [5] and [34] for the original switching lemma.

We are ready to prove the Fourier tail bounds for Boolean circuits. We define the effective size of a Boolean circuit as the number of gates in the circuit at distance 2 or more from the inputs.

► **Theorem 16.** *Let  $f$  be a Boolean circuit of depth  $d$ , effective size  $m$ , and bottom fan-in  $t$ . Then,  $\mathbf{W}^{\geq k}[f] \leq 8^{d-1} \cdot 2^{-k/(20t(96 \log(2m))^{d-2})}$ .*

**Proof.** We prove by induction on  $d$ . The base case  $d = 2$  was proved by Mansour [25], who showed that DNFs with bottom fan-in  $t$  have

$$\mathbf{W}^{\geq k}[f] \leq 4 \cdot 2^{-k/20t}.$$

For the induction step, we apply a  $p$ -random restriction with  $p = 1/48t$ . Consider the gates at distance 2 from the inputs:  $f_1, \dots, f_{m'}$ , for  $m' \leq m$ . These gates compute functions given by depth-2 circuits with bottom fan-in  $\leq t$ . Setting  $D = \lfloor kp/2 \rfloor$  and using Lemma 15 gives that with probability at least  $1 - m \cdot 2^{-D} \geq 1 - 2^{\log(m)-D}$  over the random restrictions,  $(f_i|_\rho)_{i=1}^{m'}$  can be computed by a common  $\log(2m)$ -partial decision tree of depth  $D$ . In this case, we say that the restriction  $\rho$  is *good*. Using Lemma 10 we have  $\mathbf{W}^{\geq k}[f] \leq 2 \cdot \mathbf{E}_\rho[\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho]]$ . Since  $\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho]$  is a random variable bounded in  $[0, 1]$  we have

$$\begin{aligned} \mathbf{W}^{\geq k}[f] &\leq 2 \cdot \mathbf{E}_{\rho \sim \mathcal{R}_p} [\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho]] \\ &= 2 \cdot \mathbf{E}_{\rho \sim \mathcal{R}_p} [\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho] \mid \rho \text{ is good}] \cdot \mathbf{Pr}_{\rho \sim \mathcal{R}_p} [\rho \text{ is good}] \\ &\quad + 2 \cdot \mathbf{E}_{\rho \sim \mathcal{R}_p} [\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho] \mid \rho \text{ is bad}] \cdot \mathbf{Pr}_{\rho \sim \mathcal{R}_p} [\rho \text{ is bad}] \\ &\leq 2 \cdot \mathbf{E}_{\rho \sim \mathcal{R}_p} [\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho] \mid \rho \text{ is good}] + 2 \cdot \mathbf{Pr}_{\rho \sim \mathcal{R}_p} [\rho \text{ is bad}], \end{aligned}$$

where  $\mathbf{Pr}_\rho[\rho \text{ is bad}] \leq 2^{\log(m) - \lfloor k/96t \rfloor} \leq 2^{\log(2m) - k/96t}$ . Using the following simple claim, we get  $\mathbf{Pr}_\rho[\rho \text{ is bad}] \leq 2 \cdot 2^{-k/(96t \log(2m))}$ .

► **Claim 17.** *If  $0 \leq X \leq 1$  and  $X \leq 2^{a-b}$ , where  $a \geq 1$ , then  $X \leq 2^{1-b/a}$ .*

**Proof.** Since  $0 \leq X \leq 1$  and  $a \geq 1$ , we have  $X \leq X^{1/a}$ , and  $X^{1/a}$  is at most  $2^{1-b/a}$ . ◀

We are left to analyze  $\mathbf{E}[\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho] \mid \rho \text{ is good}]$ . Fixing  $\rho$  to be some specific good restriction, we will bound  $\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho]$  for this specific  $\rho$ . By the definition of good restrictions, we have a common  $\log(2m)$ -partial decision tree of depth  $D = \lfloor kp/2 \rfloor$  computing  $(f_i|_\rho)_{i=1}^{m'}$ . For each leaf  $\ell$  of the common partial decision tree, let  $\tau_\ell$  be the restriction defined by the path leading to this leaf. We have that  $f_i|_{\tau_\ell}$  for  $i = 1, \dots, m'$  can be expressed as a decision tree of depth  $\leq \log(2m)$ , hence as a **CNF/DNF** formula of bottom fan-in at most  $\log(2m)$ . This means that applying the restriction  $\rho \circ \tau_\ell$ , the circuit  $f$  collapses to a depth  $d-1$  Boolean circuit with bottom fan-in  $t' \leq \log(2m)$  and effective size at most  $m$ .<sup>5</sup> By the induction hypothesis, for any  $k'$  we have  $\mathbf{W}^{\geq k'}[f|_{\tau_\ell}] \leq 8^{d-2} \cdot 2^{-\Omega(k'/(t' \log^{d-3}(2m)))}$ . Setting  $k' = \lfloor kp \rfloor - D \geq \lfloor kp/2 \rfloor \geq \frac{k}{96t} - 1$  and applying Lemma 13 we have

$$\begin{aligned} \mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho] &\leq \max_{\ell} \mathbf{W}^{\geq k'}[f|_{\tau_\ell}] \leq 8^{d-2} \cdot 2^{-k'/(20t' \cdot (96 \log(2m))^{d-3})} \\ &\leq 8^{d-2} \cdot 2^{1-k/(20t(96 \log(2m))^{d-2})}, \end{aligned}$$

and

$$\mathbf{W}^{\geq k}[f] \leq 4 \cdot 8^{d-2} \cdot 2^{-k/(20t(96 \log(2m))^{d-2})} + 4 \cdot 2^{-k/(96t \log(2m))} \leq 8^{d-1} \cdot 2^{-k/(20t(96 \log(2m))^{d-2})}. \blacktriangleleft$$

► **Theorem 18** (Theorem 1, restated). *Let  $f$  be an Boolean circuit of depth  $d$  and size  $m > 1$ . Then,  $\mathbf{W}^{\geq k}[f] \leq 2 \cdot 2^{-k/(c_d \log^{d-1}(m))}$  where  $c_d = 60d \cdot 192^{d-1} \leq 216^d$ . Equivalently,  $\mathbf{W}^{\geq k}[f] \leq 2 \cdot e^{-k/(c'_d \log^{d-1}(m))}$  where  $c'_d = \log_2(e) \cdot 60d \cdot 192^{d-1} \leq 2 \cdot 216^d$ .*

**Proof.** Let  $f$  be a function computed by a Boolean circuit of depth  $d$  and  $m$  gates. We add a dummy layer of fan-in 1 gates in between the inputs and the layer next to them. Thus,  $f$  is realized by an Boolean circuit of depth  $d+1$ , effective size  $m$  and bottom fan-in 1. Plugging this into Theorem 16 gives  $\mathbf{W}^{\geq k}[f] \leq 2^{3d-k/(20 \cdot 96^{d-1} \cdot \log^{d-1}(2m))}$ . Hence, by Claim 17, we get

$$\mathbf{W}^{\geq k}[f] \leq 2 \cdot 2^{-k/(3d \cdot 20 \cdot 96^{d-1} \cdot \log^{d-1}(2m))} \leq 2 \cdot 2^{-k/(60d \cdot 96^{d-1} \cdot 2^{d-1} \cdot \log^{d-1}(m))},$$

where we used  $\log(2m) \leq 2 \log(m)$  for  $m > 1$ . ◀

## 4 Applications to Pseudorandomness

### 4.1 Improving Braverman's Analysis

► **Definition 19.** Denote by  $\text{tail}(m, d, k)$  the maximal  $\mathbf{W}^{\geq k}[F]$  over all Boolean circuits  $F$  of size  $\leq m$  and depth  $\leq d$ .

By Theorem 18,  $\text{tail}(m, d, k) \leq 2 \cdot 2^{-k/(c_d \log^{d-1}(m))}$ . Braverman's Theorem can be rephrased as follows (we show that this is indeed the case in Appendix B).

► **Theorem 20** ([7]). *Let  $s_1, s_2 \geq \log m$  be any parameters. Let  $F$  be a Boolean function computed by a circuit of depth  $d$  and size  $m$ . Let  $\mu$  be an  $r$ -independent distribution where*

$$r = r(s_1, s_2, d) = 2((s_1 \cdot \log m)^d + s_2)$$

<sup>5</sup> We only introduce new gates with distance 1 from the inputs – which does not increase the effective size.

## 15:10 Tight Bounds on the Fourier Spectrum of $AC^0$

then

$$|E_{\mu}[F] - E[F]| < \varepsilon(s_1, s_2, d),$$

where  $\varepsilon(s_1, s_2, d) = 0.82^{s_1} \cdot (6m) + 2^{4(s_1 \cdot \log m)^d \log m} \cdot \text{tail}(m^3, d + 3, s_2)$

Picking  $s_1 := 5 \log(12m/\varepsilon)$  and  $s_2 := (c_{d+3} \log(m^3)^{d+2}) \cdot 8 \cdot (s_1 \cdot \log m)^d \cdot \log(m)$  we get the following corollary.

► **Theorem 21.**  $r(m, d, \varepsilon)$ -independence  $\varepsilon$ -fools Boolean circuits of depth  $d$  and size  $m$ , where

$$\begin{aligned} r(m, d, \varepsilon) &= 2((s_1 \cdot \log m)^d + s_2) \leq 4s_2 \\ &= 32 \cdot c_{d+3} \cdot (5 \log(12m/\varepsilon))^d \cdot 3^{d+2} \cdot (\log m)^{2d+3} \\ &\leq O(\log(m/\varepsilon))^d \cdot (\log m)^{2d+3}. \end{aligned}$$

### 4.2 Improving Bazzi's Analysis

Bazzi [4] showed that  $O(\log^2(m/\varepsilon))$  independence  $\varepsilon$ -fools **DNFs** of size  $m$ . We show that  $O(\log(m/\varepsilon) \cdot \log(m))$  independence suffices. For  $\varepsilon \leq 1/m^{\Omega(1)}$  this bound is tight, due to the example of Mansour from [23].

► **Theorem 22** ([4], [30]). *Let  $F$  be a **DNF** with  $m$  terms, and  $t$  be some parameter. Then,  $F$  is  $m^3 \cdot \text{tail}(m, 2, (k - 3t)/2) + m2^{-t}$  fooled by any  $k$ -wise independence.*

Picking  $t := \log(2m/\varepsilon)$  and  $k := 3t + 2c_2 \log(m) \log(4m^3/\varepsilon) = O(\log(m) \log(m/\varepsilon))$ , we get that  $k$ -wise independence  $\varepsilon$ -fools **DNFs** with  $m$  terms since

$$m^3 \cdot \text{tail}(2, m, (k - 3t)/2) + m2^{-t} \leq m^3 \cdot 2 \cdot 2^{\frac{-c_2 \log(m) \log(4m^3/\varepsilon)}{c_2 \log(m)}} + \frac{\varepsilon}{2} \leq \varepsilon.$$

## 5 On Fourier Concentration, Switching Lemmas and Influence Moments

In this section, we connect different notions of Fourier concentration of Boolean functions. We begin by introducing some new definitions, and then move to state and prove the connections between the different notions. We end this Section, with the proof of Theorem 2, which is a result of Theorem 1 and the connections established in this section.

### 5.1 Influence Moments

In this section we introduce derivatives and influences of sets of variables. A different definition to the influence of a set was made in [20]. There, the influence of a set  $J$  was defined to be the probability that under a uniform restriction of  $J^c$  to constants, the function's value is still undetermined. We choose a different variant, which has a much nicer Fourier expression.

We start with the standard definition of discrete derivatives and influences of Boolean functions.

► **Definition 23** (Discrete Derivative, Influence). Let  $f: \{-1, 1\}^n \rightarrow \mathbb{R}$  and  $i \in [n]$ . The  $i$ -th discrete derivative operator  $D_i$  maps the function  $f$  to the function  $D_i f: \{-1, 1\}^n \rightarrow \mathbb{R}$  defined by

$$D_i f(x) = \frac{f(x^{(i \rightarrow 1)}) - f(x^{(i \rightarrow -1)})}{2}.$$

where  $x^{(i \mapsto b)} = (x_1, \dots, x_{i-1}, b, x_{i+1}, \dots, x_n)$ . The influence of coordinate  $i$  on  $f$  is defined as

$$\text{Inf}_i(f) = \mathbf{E}_x[(D_i f(x))^2].$$

The generalization to sets of more than one variable is the following.

► **Definition 24** (Discrete Derivative and Influence of a Set). Let  $f: \{-1, 1\}^n \rightarrow \mathbb{R}$  and  $T \subseteq [n]$ , and write  $T = \{j_1, \dots, j_k\}$ . The  $T$ -th (discrete) derivative operator,  $D_T$ , maps the function  $f$  to the function  $D_T f: \{-1, 1\}^n \rightarrow \mathbb{R}$  defined by

$$D_T f(x) = D_{j_1} D_{j_2} \dots D_{j_k} f(x).$$

The influence of subset  $T$  on  $f$  is defined as

$$\text{Inf}_T(f) = \mathbf{E}_x[(D_T f(x))^2].$$

The following claim gives equivalent formulations for the function  $D_T f$  (and also implies that  $D_T$  is well defined, i.e., that  $D_T f$  does not depend on the order of indices in  $T$ ).

► **Claim 25.**

$$D_T f(x) = \frac{1}{2^{|T|}} \sum_{z \in \{-1, 1\}^T} f(x^{(T \mapsto z)}) \cdot \prod_{i \in T} z_i = \sum_{S \supseteq T} \hat{f}(S) \cdot \prod_{i \in S \setminus T} x_i$$

where  $x^{(T \mapsto z)}$  is the vector in  $\{-1, 1\}^n$  whose  $i$ -th coordinate equals  $z_i$  whenever  $i \in T$ , and equals  $x_i$  otherwise.

The proof uses a straightforward inductive argument, and is given for completeness in Appendix A. Note that if  $f: \{-1, 1\}^n \rightarrow \{-1, 1\}$ , then the  $T$ -th derivative of  $f$  is  $2^{-|T|}$  granular (i.e.,  $D_T f(x)$  is an integer times  $2^{-|T|}$ ), since  $D_T f(x)$  is a sum of integers divided by  $2^{|T|}$ . The following claim follows from Parseval's identity and the previous claim.

► **Claim 26.**  $\text{Inf}_T(f) = \sum_{S \supseteq T} \hat{f}(S)^2$ .

► **Definition 27** (Total Degree- $k$  Influence). The total degree- $k$  influence is defined as

$$\text{Inf}^k(f) \triangleq \sum_{T: |T|=k} \text{Inf}_T(f).$$

Claim 26 gives the following Fourier expression for the total degree- $k$  influence:

$$\text{Inf}^k(f) = \sum_{S: |S| \geq k} \hat{f}(S)^2 \cdot \binom{|S|}{k} = \sum_{d \geq k} \mathbf{W}^d[f] \cdot \binom{d}{k}. \quad (2)$$

We state the following simple lemma expressing  $\text{Inf}^k(f)$  in terms of  $\mathbf{W}^{\geq d}[f]$  instead of  $\mathbf{W}^d[f]$ .

► **Lemma 28.**  $\text{Inf}^k(f) = \sum_{d \geq k} \mathbf{W}^{\geq d}[f] \cdot \binom{d-1}{k-1}$  for all  $k \in \mathbb{N}$ .

**Proof.** We perform some algebraic manipulations on Equation (2):

$$\begin{aligned} \text{Inf}^k(f) &= \sum_{d \geq k} \mathbf{W}^d[f] \cdot \binom{d}{k} = \sum_{d \geq k} (\mathbf{W}^{\geq d}[f] - \mathbf{W}^{\geq d+1}[f]) \cdot \binom{d}{k} \\ &= \mathbf{W}^{\geq k}[f] + \sum_{d \geq k+1} \mathbf{W}^{\geq d}[f] \cdot \left( \binom{d}{k} - \binom{d-1}{k} \right) \\ &= \mathbf{W}^{\geq k}[f] + \sum_{d \geq k+1} \mathbf{W}^{\geq d}[f] \cdot \binom{d-1}{k-1} \\ &= \sum_{d \geq k} \mathbf{W}^{\geq d}[f] \cdot \binom{d-1}{k-1} \quad \blacktriangleleft \end{aligned}$$

## 5.2 Connections between Four Fourier Concentration Properties

In this section we show connections between four attributes of Boolean functions, and establish equivalence between three of them. The properties, each relative to a parameter  $t$ , are the following:

- **ESFT**: Exponentially small Fourier tails.

$$\forall k : \mathbf{W}^{\geq k}[f] \leq e^{-\Omega(k/t)} .$$

- **SLTP**: Switching lemma type property / degree shrinkage

$$\forall d, p : \Pr_{\rho \sim \mathcal{R}_p} [\deg(f|_\rho) = d] \leq O(pt)^d .$$

- **L1**: Bounded spectral norm of the  $k$ -th level.

$$\forall k : \sum_{|S|=k} |\hat{f}(S)| \leq O(t)^k .$$

- **InfK**: Bounded total degree- $k$  influence.

$$\forall k : \text{Inf}^k[f] \leq O(t)^k .$$

In Lemmata 29, 31, 32, 33, 34, 35, we show the following connections:

We remark that Lemma 35 is due to Mansour [25], and Lemma 33 is due to Linial et al. [22]. Note that **L1** does not imply any other property, because one can take for example the parity function, which has the **L1** property with  $t = 1$ . However, this function has very large Fourier tails, very high degree under random restriction, and  $\binom{n}{k}$  total degree- $k$  influence. Anything that implies **SLTP** and **L1** needs  $f$  to be Boolean. Other relations generalize to bounded real-valued functions.

In the remainder of this section we state Lemmata 29, 31, 32, 33, 34, 35 more accurately and prove them.

► **Lemma 29.** *Let  $t > 0, C > 0$ . If  $\mathbf{W}^{\geq d}[f] \leq C \cdot e^{-d/t}$  for all  $d$ , then  $\text{Inf}^k[f] \leq C \cdot t^k$  for all  $k$ .*

In the proof of Lemma 29, we use the following simple fact that follows from Newton's generalized binomial theorem.

► **Fact 30.** *Let  $|x| < 1$ , and  $k \in \mathbb{N}$ . Then,  $\sum_{d=k}^{\infty} \binom{d-1}{k-1} \cdot x^d = \frac{x^k}{(1-x)^k}$ .*

**Proof of Lemma 29.** We shall prove for  $C = 1$ , the proof generalizes for all  $C$ . Denote  $a := e^{-1/t}$ . Using Lemma 28 we bound the total degree- $k$  influence:

$$\text{Inf}^k(f) = \sum_{d \geq k} \mathbf{W}^{\geq d}[f] \cdot \binom{d-1}{k-1} \leq \sum_{d \geq k} e^{-d/t} \cdot \binom{d-1}{k-1} = \sum_{d \geq k} a^d \cdot \binom{d-1}{k-1}$$

Using Fact 30 with  $x := a$  gives

$$\text{Inf}^k(f) \leq \frac{a^k}{(1-a)^k} = \frac{1}{(1/a-1)^k} = \frac{1}{(e^{1/t}-1)^k} \leq \frac{1}{(1/t)^k} = t^k$$

where in the last inequality we used the fact that  $e^x - 1 \geq x$  for all  $x \in \mathbb{R}$ .  $\blacktriangleleft$

The reverse relation holds too, i.e. **InfK** implies **ESFT**.

► **Lemma 31.** *Let  $t > 0, C > 0$ . If  $\text{Inf}^k[f] \leq C \cdot t^k$  for all  $k$ , then  $\mathbf{W}^{\geq d}[f] \leq C \cdot e \cdot t \cdot e^{-(d-1)/et}$  for all  $d$ .*

**Proof.** We shall prove for  $C = 1$ , the proof generalizes for all  $C$ . By Lemma 28,  $\mathbf{W}^{\geq d}[f] \cdot \binom{d-1}{k-1} \leq \text{Inf}^k[f] \leq t^k$ . Hence  $\mathbf{W}^{\geq d}[f] \leq t^k / \binom{d-1}{k-1}$ . We can pick any  $k$  to optimize this bound. Picking  $k = \lfloor (d-1)/et \rfloor + 1$  we get

$$\mathbf{W}^{\geq d}[f] \leq t^k / \binom{d-1}{k-1} \leq t \cdot e^{-(k-1)} \leq e \cdot t \cdot e^{-(d-1)/et}. \quad \blacktriangleleft$$

In our previous work [33], the following relation (**ESFT** implies **SLTP**) was established.

► **Lemma 32** ([33]). *Let  $t, C > 0$ , and  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$ . If  $\mathbf{W}^{\geq k}[f] \leq C \cdot e^{-k/t}$  for all  $k$ , then  $\Pr_{\rho \sim \mathcal{R}_p}[\deg(f|_{\rho}) = d] \leq C \cdot (4pt)^d$  for all  $p, d$ .*

We give a slightly shorter proof, using the total degree- $d$  influence.

**Proof.** We shall prove for  $C = 1$ , the proof generalizes for all  $C$ . The proof goes by showing that

$$\mathbf{E}_{\rho}[\mathbf{W}^d[f|_{\rho}]] \leq (pt)^d \quad (3)$$

and

$$\mathbf{E}_{\rho}[\mathbf{W}^d[f|_{\rho}]] \geq 4^{-d} \cdot \Pr_{\rho}[\deg(f|_{\rho}) = d]. \quad (4)$$

Equation (4) is true since

$$\mathbf{E}_{\rho}[\mathbf{W}^d[f|_{\rho}]] \geq \mathbf{E}_{\rho}[\mathbf{W}^d[f|_{\rho}] | \deg(f|_{\rho}) = d] \cdot \Pr_{\rho}[\deg(f|_{\rho}) = d].$$

and the (random) Boolean function  $f|_{\rho}$  has Fourier mass at least  $4^{-d}$  if  $\deg(f|_{\rho}) = d$ , by the granularity of low degree functions – Fact 9.

We are left to prove Equation (3). Using Fact 7, we have

$$\mathbf{E}_{\rho}[\mathbf{W}^d[f|_{\rho}]] = \sum_{k=d}^n \mathbf{W}^k[f] \binom{k}{d} p^d (1-p)^{k-d} \leq p^d \sum_{k=d}^n \mathbf{W}^k[f] \binom{k}{d} = p^d \cdot \text{Inf}^d[f] \leq (pt)^d,$$

where in the last inequality we used Lemma 29.  $\blacktriangleleft$

Linial, Mansour and Nisan [22] proved that **SLTP** implies **ESFT**.

► **Lemma 33** ([22], restated slightly). *Let  $t > 0, C > 0$ , and  $f : \{-1, 1\}^n \rightarrow [-1, 1]$ . If for all  $d \in \mathbb{N}, p \in (0, 1)$ ,  $\Pr_{\rho \sim \mathcal{R}_p}[\deg(f|_{\rho}) \geq d] \leq C (tp)^d$ , then for any  $k$ ,  $\mathbf{W}^{\geq k}[f] \leq 2e \cdot C \cdot e^{-k/te}$ .*

The proof is given in [22]; we give it here for completeness.

## 15:14 Tight Bounds on the Fourier Spectrum of $\text{AC}^0$

**Proof.** Pick  $p = 1/et$ , then by Lemma 10, and the fact that  $\mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho]$  is always at most 1 and equals 0 whenever  $\deg(f|_\rho) < \lfloor kp \rfloor$ , we get

$$\mathbf{W}^{\geq k}[f] \leq 2 \mathbf{E}_\rho \left[ \mathbf{W}^{\geq \lfloor kp \rfloor}[f|_\rho] \right] \leq 2 \mathbf{E}_\rho \left[ \Pr[\deg(f|_\rho) \geq \lfloor kp \rfloor] \right] \leq 2C(1/e)^{\lfloor k/et \rfloor}. \quad \blacktriangleleft$$

The next lemma proves that **InfK** implies **L1**.

► **Lemma 34.** *If  $f$  is Boolean, then  $L_{1,k}[f] \leq 2^k \cdot \text{Inf}^k[f]$ .*

**Proof.** It is easy to see from Claim 25 that for any subset  $T \subseteq [n]$ ,

$$\mathbf{E}_x[D_T f(x)] = \mathbf{E}_x \left[ \sum_{S \supseteq T} \hat{f}(S) \prod_{i \in S \setminus T} x_i \right] = \hat{f}(T).$$

Recall that if  $f$  is Boolean, then  $D_T f(x)$  is  $2^{-|T|}$  granular, which implies that  $\forall x : |D_T f(x)| \leq 2^{|T|} (D_T f(x))^2$ . Hence,

$$|\hat{f}(T)| = |\mathbf{E}_x[D_T f(x)]| \leq \mathbf{E}_x[|D_T f(x)|] \leq 2^{|T|} \mathbf{E}_x[(D_T f(x))^2] = 2^{|T|} \text{Inf}_T(f).$$

Summing over all sets  $T$  of size  $k$  completes the proof. ◀

**Remark:** It is necessary that  $f$  is Boolean in Lemma 34, since otherwise we can have the function

$$f_{t,k}(x) = \sum_{S \subseteq [n], |S|=k} \frac{1}{\sqrt{\binom{n}{k}} e^{k/2t}} \prod_{i \in S} x_i$$

which maps  $\{-1, 1\}^n$  to  $\mathbb{R}$ , has  $\mathbf{W}^{\geq k}[f_{t,k}] = \mathbf{W}^k[f_{t,k}] = e^{-k/t}$ , and  $\text{Inf}^k[f_t] \leq t^k$ , but

$$L_{1,k}[f_t] = \sqrt{\binom{n}{k}} e^{-k/2t} \geq \left( \frac{n}{ke^{1/t}} \right)^{k/2}$$

is much larger than  $O(t)^k$  for  $n = \omega(kt^2 e^{1/t})$ .

Next, Mansour [25] proved that **SLTP** implies **L1**.

► **Lemma 35** ([25]). *Let  $t > 0$ , and  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$ . If for all  $d, p$ ,  $\Pr_{\rho \sim \mathcal{R}_p}[\deg(f|_\rho) = d] \leq C(pt)^d$ , then  $\forall k : L_{1,k}[f] \leq 2C(4t)^k$ .*

**Proof.** We shall prove for  $C = 1$ , the proof generalizes for all  $C$ . We first prove that for any function  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$ ,  $p \in [0, 1]$ ,  $k \in \mathbb{N}$  we have  $L_{1,k}(f) \leq \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p}[L_{1,k}[f|_\rho]]$ .

$$\begin{aligned} L_{1,k}[f] &= \sum_{S:|S|=k} |\hat{f}(S)| = \sum_{S:|S|=k} \left| \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p} \left[ \widehat{f|_\rho}(S) \right] \right| && \text{(Fact 6)} \\ &\leq \sum_{S:|S|=k} \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p} \left[ |\widehat{f|_\rho}(S)| \right] = \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p} \left[ \sum_{S:|S|=k} |\widehat{f|_\rho}(S)| \right] \\ &= \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p} [L_{1,k}[f|_\rho]]. \end{aligned} \quad (5)$$

Next, we show that for  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$ , if there exists  $t > 0$  such that for all  $d, p$ ,  $\Pr[\deg(f|_\rho) = d] \leq (pt)^d$ , then  $\mathbf{E}_{\rho \sim \mathcal{R}_p}[L_1[f|_\rho]] \leq 2$  for  $p = 1/4t$ . Conditioning on  $\deg(f|_\rho) = d$  and using Fact 9, we have  $L_1[f|_\rho] \leq 2^d$ . Hence,

$$\mathbf{E}_{\rho \sim \mathcal{R}_p}[L_1[f|_\rho]] = \sum_{d=0}^n \mathbf{E}_{\rho \sim \mathcal{R}_p}[L_1[f|_\rho] | \deg(f|_\rho) = d] \cdot \Pr[\deg(f|_\rho) = d] \leq \sum_{d=0}^n 2^d \cdot \left(\frac{1}{4}\right)^d \leq 2. \quad (6)$$

Plugging Equation (6) in Equation (5) with  $p = 1/4t$  we get

$$L_{1,k}[f] \leq \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p}[L_{1,k}[f|_\rho]] \leq \frac{1}{p^k} \mathbf{E}_{\rho \sim \mathcal{R}_p}[L_1[f|_\rho]] \leq (4t)^k \cdot 2. \quad \blacktriangleleft$$

The next lemma is relevant to the learnability results given in [25] and [22].

► **Lemma 36.** *Let  $f$  be a Boolean function, let  $t \geq 1$  and  $C$  be some positive constant. If  $\mathbf{W}^{\geq k}[f] \leq C \cdot e^{-k/t}$  for all  $k$ , then  $f$  is  $\varepsilon$ -concentrated on at most  $t^{O(t \log(1/\varepsilon))}$  Fourier coefficients.*

Here, by  $\varepsilon$ -concentrated on  $r$  coefficients we mean that there exist  $r$  subsets of  $[n]$ ,  $\{S_1, \dots, S_r\}$ , which captures  $1 - \varepsilon$  of the Fourier mass of  $f$ , i.e.  $\sum_{i=1}^r \hat{f}(S_i)^2 \geq 1 - \varepsilon$ .

**Proof.** We shall prove for  $C = 1$ , the proof generalizes for all constant  $C$ . Let  $w := t \cdot \ln(2/\varepsilon)$ . First it is enough to consider Fourier coefficients of sets of size  $\leq w$ , since the sum of squares of Fourier coefficients of larger sets is at most  $\varepsilon/2$ . Now  $\sum_{S:|S| \leq w} |\hat{f}(S)| = \sum_{i=0}^w L_{1,i}[f]$ . Using Lemmata 29 and 34 we get

$$\sum_{i=0}^w L_{1,i}[f] \leq \sum_{i=0}^w 2^i t^i \stackrel{(t \geq 1)}{\leq} t^w 2^{w+1}.$$

Letting  $\mathcal{F} = \{S : |S| \leq w, |\hat{f}(S)| \geq \frac{\varepsilon/2}{t^w 2^{w+1}}\}$  we get by Parseval's identity that

$$\sum_{S \in \mathcal{F}} \hat{f}(S)^2 = 1 - \sum_{|S| > w} \hat{f}(S)^2 - \sum_{|S| \leq w, S \notin \mathcal{F}} \hat{f}(S)^2,$$

where we already noted that  $\sum_{|S| > w} \hat{f}(S)^2 \leq \varepsilon/2$ . To bound the last term

$$\sum_{|S| \leq w, S \notin \mathcal{F}} \hat{f}(S)^2 \leq \max\{|\hat{f}(S)| : |S| \leq w, S \notin \mathcal{F}\} \cdot \sum_{|S| \leq w} |\hat{f}(S)| \leq \varepsilon/2.$$

Hence,  $\sum_{S \in \mathcal{F}} \hat{f}(S)^2 \geq 1 - \varepsilon$ . It remain to figure out the size of  $\mathcal{F}$ . Since every coefficient in  $\mathcal{F}$  contributes at least  $\frac{\varepsilon/2}{t^w 2^{w+1}}$  to the sum  $\sum_{i=0}^w L_{1,i}[k]$ , and this sum is at most  $t^w 2^{w+1}$  we get that the size of  $\mathcal{F}$  is at most  $2(t^w 2^{w+1})^2 / \varepsilon = O(t)^{2t \ln(1/\varepsilon)}$ , which completes the proof. ◀

### 5.3 Theorem 2

Immediate from Theorem 18, Lemmata 29, 32, 34, and 36 we get the following corollary.

► **Theorem 37** (Thm. 2, restated). *Let  $f$  be a Boolean circuit of depth  $d$  and size  $m > 1$ . Then,*

1. *For all  $k, p$ ,  $\Pr_{\rho \sim \mathcal{R}_p}[\deg(f|_\rho) = k] \leq 2 \cdot (4p \cdot c'_d \log^{d-1}(m))^k$ .*
2. *For all  $k$ ,  $\text{Inf}^k[f] \leq 2 \cdot (c'_d \log^{d-1}(m))^k$ .*
3. *For all  $k$ ,  $L_{1,k}[f] = \sum_{S:|S|=k} |\hat{f}(S)| \leq 2 \cdot (2c'_d \log^{d-1}(m))^k$ .*
4.  *$f$  is  $\varepsilon$ -concentrated on at most  $O(\log^{d-1} m)^{O(\log^{d-1}(m) \log(1/\varepsilon))} = 2^{O(\log \log(m) \log^{d-1}(m) \log(1/\varepsilon))}$  Fourier coefficients.*

## 6 Short Proofs for Known Results

In this section, we give simple proofs for two known results based on Theorem 37.

### 6.1 Bounded-Depth Circuits Cannot Approximate Majority

The next result states that nearly balanced symmetric functions, and in particular the Majority function, cannot be well approximated by a small and shallow circuit.

► **Theorem 38.** *Let  $g : \{-1, 1\}^n \rightarrow \{-1, 1\}$  be a symmetric function on  $n$  variables. Let  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$  be depth  $d$  size  $m$  circuit, and assume that*

$$c'_d \log^{d-1}(m) \leq (n/100 \ln(n))^{1/3}.$$

Then,

$$\text{Cor}(f, g) \triangleq \left| \mathbf{E}_x[f(x)g(x)] \right| \leq |\hat{g}(\emptyset)| + \frac{\sqrt{2} + 8c'_d \log^{d-1}(m)}{\sqrt{n}}$$

**Proof.** Since  $g$  is a symmetric Boolean function, for all  $S \subseteq [n]$ ,  $\hat{g}(S)^2 \cdot \binom{n}{|S|} = \sum_{T:|T|=|S|} \hat{g}(T)^2 \leq 1$ . Hence,  $|\hat{g}(S)| \leq \frac{1}{\sqrt{\binom{n}{|S|}}}$ . Let  $\ell$  be some parameter we shall set later. Then,

$$\left| \mathbf{E}_x[f(x)g(x)] \right| \leq \sum_S |\hat{f}(S)\hat{g}(S)| = |\hat{f}(\emptyset)\hat{g}(\emptyset)| + \sum_{k=1}^{\ell} \sum_{S:|S|=k} |\hat{f}(S)\hat{g}(S)| + \sum_{S:|S|>\ell} |\hat{f}(S)\hat{g}(S)|. \quad (7)$$

We bound each of the three terms in the RHS of Equation (7). The first term is at most  $|\hat{g}(\emptyset)|$ . For the third term we use Cauchy-Schwartz, Theorem 18, and Parseval's identity ( $\sum_{S:|S|>\ell} \hat{g}(S)^2 \leq 1$ ), to get

$$\sum_{S:|S|>\ell} |\hat{f}(S)\hat{g}(S)| \leq \sqrt{\sum_{S:|S|>\ell} \hat{f}(S)^2} \sqrt{\sum_{S:|S|>\ell} \hat{g}(S)^2} \leq \sqrt{2 \cdot e^{-\ell/(c'_d \log^{d-1}(m))}}.$$

Picking  $\ell := \ln(n) \cdot c'_d \log^{d-1}(m)$  this is smaller than  $\sqrt{2/n}$ . For the second term in the RHS of Equation (7), we use the estimates on  $L_{1,k}(f)$  and  $|\hat{g}(S)|$ , to get

$$\sum_{S:|S|=k} |\hat{g}(S)\hat{f}(S)| \leq \frac{1}{\sqrt{\binom{n}{k}}} \cdot \sum_{S:|S|=k} |\hat{f}(S)| \leq \frac{2 \cdot (2c'_d \log^{d-1}(m))^k}{\sqrt{\binom{n}{k}}} \leq 2 \cdot \left( \frac{2c'_d \log^{d-1}(m)}{\sqrt{n/k}} \right)^k.$$

We denote by  $D_k := 2 \cdot \left( \frac{2c'_d \log^{d-1}(m)}{\sqrt{n/k}} \right)^k$ . The ratio between two consecutive terms  $D_{k+1}/D_k$  for  $k+1 \leq \ell$  is at most

$$\frac{2c'_d \log^{d-1}(m)}{\sqrt{n}} \sqrt{\frac{(k+1)^{k+1}}{k^k}} \leq \frac{2c'_d \log^{d-1}(m)}{\sqrt{n}} \sqrt{e \cdot (k+1)} \leq \frac{2c'_d \log^{d-1}(m)}{\sqrt{n}} \sqrt{e \cdot \ell} \leq \frac{1}{2},$$

where we used the choice of  $\ell$  and the assumption  $c'_d \log^{d-1}(m) \leq \left(\frac{n}{100 \ln n}\right)^{1/3}$  for the last inequality to hold. We get that the sum  $\sum_{1 \leq |S| \leq \ell} |\hat{f}(S)\hat{g}(S)|$  is at most  $D_1 + D_2 + \dots + D_\ell \leq 2D_1$ . Overall, we get

$$\mathbf{E}_x[f(x)g(x)] \leq |\hat{g}(\emptyset)| + \frac{\sqrt{2} + 8c'_d \log^{d-1}(m)}{\sqrt{n}}. \quad \blacktriangleleft$$

We remark that although our proof is Fourier analytical, it differs from the standard argument that is used to bound the correlation of bounded depth circuits with parity for example. The standard argument shows that two functions are  $o(1)$  correlated by proving that one is  $1 - o(1)$  concentrated on the low levels of the Fourier spectrum while the other is  $1 - o(1)$  concentrated on the high levels. Here, however, if we take  $g$  to be the Majority function, and  $f$  to be an  $\mathbf{AC}^0$  circuit, then both  $f$  and  $g$  are 0.99-concentrated on the first  $O(\text{poly log}(n))$  levels of their Fourier spectrum. We deduce the small correlation by showing that  $f$  must be very imbalanced on those levels, which is captured by having small  $L_{1,k}$  norm. In contrast, the Majority function is symmetric – its Fourier mass on level  $k$  is equally spread on the different coefficients. Combining these two properties guarantees small correlation.

## 6.2 The Coin-Problem

► **Theorem 39.** *Let  $f : \{-1, 1\}^n \rightarrow \{-1, 1\}$  be a depth  $d$  size  $m$  circuit, and let  $p \in [0, 1]$ . Then,  $f$  distinguishes between unbiased coins and coins with bias  $p$  with advantage at most  $6c'_d p \log^{d-1}(m)$ .*

**Proof.** We can assume  $pc'_d \log^{d-1}(m) \leq 1/6$ , since otherwise the result is trivial. For  $-1 \leq p \leq 1$ , a  $p$ -biased coin is a random variable which gets 1 with probability  $(1+p)/2$  and  $-1$  with probability  $(1-p)/2$ , i.e., this is a biased coin whose expectation is  $p$ . Let  $U_n$  be the distribution of  $n$  independent 0-biased coins, and  $B(n, p)$  be the distribution of  $n$  independent  $p$ -biased coins. We have

$$\begin{aligned} \text{Distinguishability}(f) &\triangleq \left| \mathbf{E}_{x \sim U_n} [f(x)] - \mathbf{E}_{x \sim B(p, n)} [f(x)] \right| = \left| \hat{f}(\emptyset) - \sum_{S \subseteq [n]} \hat{f}(S) p^{|S|} \right| \\ &= \left| \sum_{S \neq \emptyset} \hat{f}(S) p^{|S|} \right| \leq \sum_{k=1}^n p^k \cdot 2 \cdot \left( 2c'_d \log^{d-1}(m) \right)^k \\ &\leq 2p \cdot \left( 2c'_d \log^{d-1}(m) \right) \cdot \sum_{k=1}^{\infty} (1/3)^{k-1} = 3p \cdot \left( 2c'_d \log^{d-1}(m) \right). \quad \blacktriangleleft \end{aligned}$$

## 7 A New Proof for Håstad's Switch-Many Lemma

In this section, we give a new proof for Håstad's [16] Switch-Many Lemma, i.e., Lemma 15. The new proof follows Razborov's [29] approach, and its recent simplification by Thapen [34] for Håstad's original switching lemma [14].

**Notation.** We denote by  $\mathcal{R}$  the set of all restrictions on  $n$  variables. For a sequence of indices  $S \in [n]^k$  with no repetitions, and a string  $\sigma \in \{0, 1\}^k$  we denote by  $(S \rightarrow \sigma)$  the restriction which fixes  $S_i$  to  $\sigma_i$  for  $i \in [k]$  and leaves all other variables free. For two restrictions  $\rho, \sigma$  we denote by  $\rho\sigma$  their composition. For a sequence  $S \in \Sigma^k$  over some alphabet  $\Sigma$ , and two indices  $i$  and  $j$  such that  $1 \leq i \leq j \leq k$ , we denote by  $S[i : j]$  the subsequence  $(S_i, \dots, S_j)$ , and by  $S[i]$  the element  $S_i$ .

### 7.1 The Canonical Decision Tree

Let  $F$  be an  $r$ -DNF, i.e., an OR of ANDs where each AND has at most  $r$  input literals from  $x_1, \dots, x_n, \neg x_1, \dots, \neg x_n$ . Let  $\rho$  be a restriction. The canonical tree  $T(F, \rho)$  is defined by the following decision procedure: Look through  $F$  for the first term  $C_1$ , such that  $C_1|_{\rho} \neq 0$ . If no

## 15:18 Tight Bounds on the Fourier Spectrum of $\text{AC}^0$

such term exists, then halt and output 0. Otherwise, let  $A$  be the set of free variables in  $C_1$  under  $\rho$ . Query the variables in  $A$  and let  $\pi_1, \dots, \pi_{|A|}$  be their assignment. If the term  $C_1$  is satisfied under the assignment (in particular if  $A = \emptyset$ ), then halt and output 1. Otherwise, repeat the process with  $\rho(A \rightarrow (\pi_1, \pi_2, \dots, \pi_{|A|}))$  instead of  $\rho$ . We keep iterating until one of the aforementioned halting conditions hold.

### 7.2 Restriction Tree for Multiple DNFs

Let  $F_1, \dots, F_m$  be  $r$ -DNFs. We define the  $d$ -restriction-tree complexity of  $F_1, \dots, F_m$  to be the minimal depth of a restriction tree such that under the restriction defined by each leaf, each DNF  $F_i$  is of canonical decision-tree-complexity at most  $d$ . We denote this complexity by  $\text{RT}_d(\{F_1, \dots, F_m\})$ .

► **Theorem 40.**

$$\Pr_{\rho \sim \mathcal{R}_p} [\text{RT}_d(\{F_1|_\rho, \dots, F_m|_\rho\}) \geq k] \leq m^{\lceil k/(d+1) \rceil} \cdot \left( \frac{24pr}{1-p} \right)^k.$$

The following is a corollary of Theorem 40.

► **Corollary 41.** *Let  $F_1, \dots, F_m$  be  $r$ -DNFs. Let  $k, d$  be positive integers,  $0 \leq p \leq 1$ , and assume  $2^{d+1} \geq m$ . Then,*

$$\Pr_{\rho \sim \mathcal{R}_p} [\text{RT}_d(\{F_1|_\rho, \dots, F_m|_\rho\}) \geq k] \leq m \cdot (49pr)^k. \quad (8)$$

**Proof.** We can assume without loss of generality that  $p < 1/49$  since otherwise the RHS of Eq. (8) is at least 1 and the LHS is always at most 1. We get

$$\begin{aligned} \Pr_{\rho \sim \mathcal{R}_p} [\text{RT}_d(\{F_1|_\rho, \dots, F_m|_\rho\}) \geq k] &\leq m^{\lceil k/(d+1) \rceil} \cdot (24pr/(1-p))^k && \text{(Theorem 40)} \\ &\leq m^{1+k/(d+1)} \cdot (24pr/(1-p))^k \\ &= m \cdot \left( \frac{m^{1/(d+1)} \cdot 24pr}{1-p} \right)^k \\ &\leq m \cdot \left( \frac{2 \cdot 24pr}{1-p} \right)^k && (m \leq 2^{d+1}) \\ &\leq m \cdot (49pr)^k. && (1-p > 48/49) \end{aligned}$$

◀

We will prove Theorem 40 based on the approach of Thapen [34] which simplified Razborov's [29] and Beame's [5] proofs for the (original) switching lemma. The idea of the proof is that in order to show that some event  $A$  happens with low probability, it is sufficient to show that there exists some other event  $B$  (not necessarily disjoint of  $A$ ) that happens with probability much larger than  $A$ . For example, if  $\Pr[B] \geq M \cdot \Pr[A]$  (think of  $M$  as some large factor) then since  $\Pr[B] \leq 1$  it means that  $\Pr[A] \leq 1/M$ .

The following is the main lemma in this section, from which we deduce Theorem 40 quite easily.

► **Lemma 42.** *Let  $S$  be the set of restrictions under which  $\text{RT}_d(\{F_1|_\rho, \dots, F_m|_\rho\}) \geq k$ . Then, there is a 1:1 mapping*

$$\theta : S \rightarrow \mathcal{R} \times [3r]^k \times \{0, 1\}^k \times \{0, 1\}^k \times [m]^{\lceil k/d+1 \rceil}$$

given by  $\theta : \rho \mapsto (\rho\sigma, \beta, \pi, \tau, \mathcal{I})$  where  $\sigma$  fixes exactly  $k$  additional variables that weren't fixed by  $\rho$ .

**Proof of Theorem 40, assuming Lemma 42.** For a (fixed) restriction  $\rho \in \mathcal{R}$  we denote by  $\Pr[\rho]$  the probability to sample  $\rho$  when sampling a restriction from the distribution  $\mathcal{R}_p$ . For a (fixed) set of restrictions  $A \subseteq \mathcal{R}$  we denote by  $\Pr[A]$  the probability to sample a restriction in  $A$  when sampling a restriction from the distribution  $\mathcal{R}_p$ . Recall that by the definition of  $\mathcal{R}_p$ , we have  $\Pr[\rho] = p^a \cdot \left(\frac{1-p}{2}\right)^{b+c}$  where  $a, b$  and  $c$  are the number of  $*$ 's, 0's and 1's in  $\rho$  respectively.

For a fixed value of  $\beta, \pi, \tau$ , and  $\mathcal{I}$ , consider the set  $S' = S_{\beta, \pi, \tau, \mathcal{I}} := \{\rho \in S \mid \exists \rho' : \theta(\rho) = (\rho', \beta, \pi, \tau, \mathcal{I})\}$ . Since  $\theta$  is 1:1 (Lemma 42), the first component  $\theta_1 : \rho \mapsto \rho\sigma$  is also 1:1 on the set  $S'$ .<sup>6</sup> This implies that  $\Pr[\theta_1(S')] = \sum_{\rho \in S'} \Pr[\theta_1(\rho)]$ . By the definition of  $\mathcal{R}_p$ , for any  $\rho \in \mathcal{R}$  and any  $\sigma$  that fixes  $k$  additional variables that were free in  $\rho$ , we have  $\Pr[\rho\sigma] = \left(\frac{1-p}{2p}\right)^k \cdot \Pr[\rho]$ . We get

$$1 \geq \Pr[\theta_1(S')] = \sum_{\rho \in S'} \Pr[\theta_1(\rho)] = \sum_{\rho \in S'} \Pr[\rho] \cdot \left(\frac{1-p}{2p}\right)^k = \Pr[S'] \cdot \left(\frac{1-p}{2p}\right)^k,$$

hence,  $\Pr[S'] \leq \left(\frac{2p}{1-p}\right)^k$ . Taking a union bound over all possible  $\beta, \pi, \tau, \mathcal{I}$  we get, as desired,

$$\Pr[S] \leq \sum_{\beta, \pi, \tau, \mathcal{I}} \Pr[S_{\beta, \pi, \tau, \mathcal{I}}] \leq (3r)^k \cdot 2^k \cdot 2^k \cdot m^{\lceil k/(d+1) \rceil} \cdot \left(\frac{2p}{1-p}\right)^k. \quad \blacktriangleleft$$

**Proof of Lemma 42.** Let  $\rho \in S$  be a restriction such that  $\text{RT}_d(\{F_1|_\rho, \dots, F_m|_\rho\}) \geq k$ . We describe in detail how to map  $\rho$  into  $(\rho\sigma, \beta, \pi, \tau, \mathcal{I})$ , where  $\sigma \in \mathcal{R}$ ,  $\beta \in [3r]^k$ ,  $\pi \in \{0, 1\}^k$ ,  $\tau \in \{0, 1\}^k$ , and  $\mathcal{I} \in [m]^{\lceil k/(d+1) \rceil}$ . Then, we shall describe how to decode from  $(\rho\sigma, \beta, \pi, \tau, \mathcal{I})$  the restriction  $\rho$ , showing that the mapping is 1:1.

**Encoding.** We are going to choose a sequence of  $k$  variables that weren't fixed by  $\rho$ , and assign them values according to three adversarial strategies:

**Global Strategy.** This strategy ensures that  $\text{RT}_d(\{F_1|_\rho, \dots, F_m|_\rho\}) \geq k$ . We will denote its answers by  $\pi_1, \dots, \pi_k \in \{0, 1\}$ .

**Local Strategy.** This will be the local adversary strategy based on one **DNF** we are focusing on. We will denote its answers by  $\tau_1, \dots, \tau_k \in \{0, 1\}$ .

**Bread-Crumbs Strategy.** The objective of this strategy is to leave the necessary traces, so that the mapping will be invertible. We will denote its answers by  $\sigma_1, \dots, \sigma_k \in \{0, 1\}$ .

We consider the following iterative encoding process, which is divided into phases. Each phase, except for maybe the last phase, contains at least  $d+1$  steps. In each phase,  $t$ , we will focus on one specific **DNF** out of  $F_1, \dots, F_m$ , and identify a sequence of variables  $T_t$  of length  $d_t \geq d+1$  to be queried. The strings  $\pi^t, \tau^t, \sigma^t \in \{0, 1\}^{d_t}$  will be the answers to the sequence of queries  $T_t$  according to the Global, Local or Bread-Crumbs strategies, respectively.

At phase  $t = 1, 2, \dots$ , we consider the restriction  $\rho_t = \rho(T_1 \rightarrow \pi^1) \dots (T_{t-1} \rightarrow \pi^{t-1})$ . We identify some **DNF**,  $F_{i_t}$ , whose canonical decision tree depth under  $\rho_t$  is  $d_t \geq d+1$  (if no such **DNF** exists, then we stop). We add  $i_t$  to  $\mathcal{I}$ . Next, we run the canonical decision tree on  $F_{i_t}$  and  $\rho_t$ , answering according to the local adversarial strategy which keeps  $F_{i_t}$  undetermined after less than  $d_t$  queries.

<sup>6</sup> Since a collision in  $\theta_1$  on  $S'$  implies a collision in  $\theta$ .

We initialize  $T_t := \emptyset$  and  $\tau^t, \sigma^t$  to be empty-strings. In each step, we find the first term  $\mathcal{T}$  in  $F_{i_t}$  which is not equivalent to 0 under  $\rho_t(T_t \rightarrow \tau^t)$ . By the assumption that  $F_{i_t}$  has canonical decision tree depth  $d_t$ , we get that  $\mathcal{T}$  is not equivalent to 1 either. Let  $A$  be the non-empty set of variables whose literals appear in  $\mathcal{T}$  and are unassigned by  $\rho_t$ . We order the set  $A$  in some canonical order. For each  $x_j \in A$ , let  $j_{\text{ind}} \in [r]$  be the index of the literal containing  $x_j$  in term  $\mathcal{T}$ . We let  $j_{\text{type}} = 1$  if  $x_j$  is the last variable to be queried in the DNF  $F_{i_t}$ , otherwise  $j_{\text{type}} = 2$  if  $x_j$  is the last variable in  $A$ , and otherwise  $j_{\text{type}} = 3$ . For each  $x_j \in A$ , according to the  $A$ 's order, we add  $(j_{\text{ind}}, j_{\text{type}})$  to  $\beta$ . In addition, we query the local adversary according to the variables in  $A$  under the restriction  $\rho_t \cdot (T_t \rightarrow \tau^t)$  and update  $\tau^t$  to contain its new answers. We concatenate to  $\sigma^t$  the values to the variables in  $A$  that satisfy  $\mathcal{T}$  (these are the ‘‘bread-crumbs’’). We update  $T_t := T_t \cup A$ , and continue with  $\rho_t \cdot (T_t \rightarrow \tau^t)$  until querying  $d_t$  variables.

After ending the phase, we ask the global adversary the sequence of queries in  $T_t$  (by the order they were asked) and consider its sequence of answers as  $\pi^t$ . We continue to the next phase with  $\rho_{t+1} = \rho(T_1 \rightarrow \pi^1) \dots (T_t \rightarrow \pi^t)$  (i.e., we ‘‘discard’’ the answers to  $T_t$  according to the local adversary and add the answers according to the global adversary). We stop the encoding process after querying  $k$  variables overall, even if we are in the middle of a phase.

We show by induction that  $\text{RT}_d(\{F_1|_{\rho_t}, \dots, F_m|_{\rho_t}\}) \geq k - \sum_{i=1}^{t-1} d_i$ . This is trivially true for  $t = 1$  since this is equivalent to the assumption that  $\rho \in S$ . Assuming it is true for  $t$ , we show that it is true for  $t + 1$ . Since  $\text{RT}_d(\{F_1|_{\rho_t}, \dots, F_m|_{\rho_t}\}) \geq k - \sum_{i=1}^{t-1} d_i$  it means that there exists a set of answers for  $T_t$ , namely  $\pi^t$ , under which  $\text{RT}_d(\{F_1|_{\rho_{t+1}}, \dots, F_m|_{\rho_{t+1}}\}) \geq k - \sum_{i=1}^{t-1} d_i - |T_t| = k - \sum_{i=1}^t d_i$ , which completes the induction.

Let  $p$  be the number of phases in the encoding process. By the above process, we get that  $\pi = \pi^1 \dots \pi^p \in \{0, 1\}^k$ ,  $\tau = \tau^1 \dots \tau^p \in \{0, 1\}^k$ ,  $\beta \in [3r]^k$ ,  $\sigma := (T_1 \rightarrow \sigma^1) \dots (T_p \rightarrow \sigma^p)$  fixes  $k$  additional variables to those fixed by  $\rho$ , and  $\mathcal{I}$  is a sequence of  $p$  indices from  $[m]$ . In addition,  $p \leq \lceil k/(d+1) \rceil$  since in each phase, except for maybe the last phase, we query at least  $d+1$  variables and overall we query at most  $k$  variables. If less than  $\lceil k/(d+1) \rceil$  phases exists, we may pad  $\mathcal{I}$  with 1's.

**Decoding.** We wish to show that  $\theta$  is 1:1. Let  $(\rho\sigma, \beta, \pi, \tau, \mathcal{I})$  be an image of  $\theta$ ; we will show how to decode  $\rho$  from this image. It is enough to show by induction on  $t = 1, \dots, p$ , that we can recover  $T_1, \dots, T_t$ , since this allows to reconstruct  $\rho$  by simply setting the values of  $\bigcup_{i=1}^p T_i$  to  $*$  in  $\rho\sigma$ .

Assuming we already recovered  $T_1, \dots, T_{t-1}$  correctly, we show how to decode  $T_t$  as well. Knowing  $T_1, \dots, T_{t-1}$  allows the decoder to define  $\rho'_t := \rho(T_1 \rightarrow \pi^1) \dots (T_{t-1} \rightarrow \pi^{t-1})(T_t \rightarrow \sigma^t) \dots (T_p \rightarrow \sigma^p)$  by replacing the assignment of  $T_1, \dots, T_{t-1}$  in  $\rho\sigma$  according to  $\pi^1, \dots, \pi^{t-1}$ . Using the set of indices  $\mathcal{I}$ , we know  $i_t$ , i.e. the index of the **DNF** out of  $F_1, \dots, F_m$  that was considered by the encoding process at phase  $t$ . We show that the first term in  $F_{i_t}$  under  $\rho'_t$  which is not equivalent to 0 is the same as the first such term under  $\rho_t$  (recall that  $\rho_t := \rho(T_1 \rightarrow \pi^1) \dots (T_{t-1} \rightarrow \pi^{t-1})$ ). Let  $i'$  be the index of the first nonzero term in  $F_{i_t}$  under  $\rho_t$ . Then, all terms prior to  $i'$  were fixed to 0 under  $\rho_t$  and this remains true when we refine  $\rho_t$  to  $\rho'_t$ . In addition, since  $\sigma^t$  satisfies all the literals in term  $i'$  which are unassigned by  $\rho_t$  (except if we finished the entire encoding process while in the middle of processing this term, in this case  $\sigma^t$  fixes some of the free variables to satisfy the literals and the rest remain free), we get that the term with index  $i'$  in  $F_{i_t}$  is not equivalent to 0 under  $\rho'_t$ . Thus, we identified the term  $i'$  correctly. We collect indices from  $\beta$  until reaching type 1 or 2, which yields the set of variables the encoder sets when processing term  $i'$ . We replace the assignment for these variables to be according to  $\tau$  instead of according to  $\sigma$ .

We continue this way by identifying the next term the encoder examined, and decode the set of variables fixed in the encoding process, according to the information stored in  $\beta$ . This allows us to continue decoding the set  $T_t$  which completes the proof. ◀

► **Remark.** We remark that the information we are avoiding to store<sup>7</sup> is the index of the term on which a certain **DNF** is not fixed under a restriction  $\rho$ . We are using the Bread-Crumbs partial assignment  $\sigma$  to satisfy all the literals that are unassigned in this term, in order to allow the identification of the term in the decoding process. Once the term is known, we can encode/decode a variable using a number in  $[r]$  rather than a number in  $[n]$ , which is much more “efficient” to encode. Storing the index to the DNF we are considering at each phase may seem “expensive”. However, we are recording such an index at most once every  $d + 1$  consecutive steps, making this reasonable.

**Acknowledgements.** I wish to thank my advisor Ran Raz for many helpful discussions, for his encouragement and his support. I thank Johan Håstad and Roei Tell for helpful discussions. I thank the anonymous referees for helpful comments.

## **A** Equivalent Expressions for the $T$ -th Discrete Derivatives

► **Claim** (Claim 25, restated).

$$D_T f(x) = \frac{1}{2^{|T|}} \sum_{z \in \{-1, 1\}^T} f(x^{(T \mapsto z)}) \cdot \prod_{i \in T} z_i = \sum_{S \supseteq T} \hat{f}(S) \cdot \prod_{i \in S \setminus T} x_i$$

where  $x^{(T \mapsto z)}$  is the vector in  $\{-1, 1\}^n$  whose  $i$ -th coordinate equals  $z_i$  whenever  $i \in T$ , and  $x_i$  otherwise.

**Proof.** We prove by induction on the size of  $T$ . For  $T = \emptyset$  the claim trivially holds. For  $T = \{j_1, \dots, j_k\}$ , let  $T' = \{j_2, \dots, j_k\}$  and  $g = D_{T'}f$ , then  $D_T f = D_{j_1} D_{T'} f = D_{j_1} g$ . By the definition of the  $j_1$ -th derivative, we have

$$D_T f(x) = \frac{g(x^{(j_1 \mapsto 1)}) - g(x^{(j_1 \mapsto -1)})}{2}.$$

By the induction hypothesis, this equals

$$\begin{aligned} D_T f(x) &= \frac{1}{2} \cdot \left( D_{T'} f(x^{(j_1 \mapsto 1)}) - D_{T'} f(x^{(j_1 \mapsto -1)}) \right) \\ &= \frac{1}{2} \frac{1}{2^{k-1}} \cdot \left( \sum_{z' \in \{-1, 1\}^{T'}} f \left( \left( x^{(j_1 \mapsto 1)} \right)^{(T' \mapsto z')} \right) \prod_{i \in T'} z'_i \right. \\ &\quad \left. - \sum_{z' \in \{-1, 1\}^{T'}} f \left( \left( x^{(j_1 \mapsto -1)} \right)^{(T' \mapsto z')} \right) \prod_{i \in T'} z'_i \right) \\ &= \frac{1}{2^k} \sum_{z \in \{-1, 1\}^T} f(x^{(T \mapsto z)}) \prod_{i \in T} z_i. \end{aligned}$$

As for the second item, by induction,  $g(x) = \sum_{S \supseteq T'} \hat{f}(S) \cdot \prod_{i \in S \setminus T'} x_i$ . Thus,

$$\begin{aligned} D_T f(x) &= \frac{g(x^{(j_1 \mapsto 1)}) - g(x^{(j_1 \mapsto -1)})}{2} = \frac{1}{2} \sum_{S \supseteq T'} \hat{f}(S) \cdot \prod_{i \in S \setminus T} x_i \cdot \begin{cases} 1 - (-1), & j_1 \in T' \\ 1 - 1, & \text{otherwise} \end{cases} \\ &= \sum_{S \supseteq T} \hat{f}(S) \cdot \prod_{i \in S \setminus T} x_i. \quad \blacktriangleleft \end{aligned}$$

## B Rephrasing Braverman's Result

► **Lemma 43** ([7, Lemma 8]). *Let  $\nu$  be any probability distribution on  $\{0, 1\}^n$ . For a circuit of depth  $d$  and size  $m$  computing a function  $F$ , for any  $s$ , there is a degree  $r = (s \cdot \log(m))^d$  polynomial  $f$  and a Boolean function  $\mathcal{E}_\nu$  computable by a circuit of depth  $\leq d + 3$  and size  $O(m^2 r)$  such that*

1.  $\Pr_\nu[\mathcal{E}_\nu(x) = 1] < 0.82^s \cdot m$ , and
2. whenever  $\mathcal{E}_\nu = 0$ ,  $f(x) = F(x)$ .

► **Proposition 44** ([7, Prop. 9]). *In Lemma 43, for  $s \geq \log(m)$ ,  $\|f\|_\infty < (2m)^{\deg(f)-2} = (2m)^{(s \log(m))^d - 2}$*

► **Lemma 45** ([7, Rephrasing of Lemma 10]). *Let  $F$  be computed by a circuit of depth  $d$  and size  $m$ . Let  $s_1, s_2$  be two parameters with  $s_1 \geq \log(m)$ . Let  $\mu$  be any probability distribution on  $\{0, 1\}^n$ , and  $U_{\{0, 1\}^n}$  be the uniform distribution on  $\{0, 1\}^n$ . Set*

$$\nu := \frac{1}{2} (\mu + U_{\{0, 1\}^n}).$$

*Let  $\mathcal{E}_\nu$  be the function from Lemma 8 with  $s = s_1$ . Set  $F' = F \vee \mathcal{E}_\nu$ . Then, there is a polynomial  $f'$  of degree  $r_f = (s_1 \cdot \log m)^d + s_2$ , such that*

1.  $\Pr_\mu[F \neq F'] < 2 \cdot 0.82^{s_1} \cdot m$
2.  $\Pr_U[F \neq F'] < 2 \cdot 0.82^{s_1} \cdot m$
3.  $\|F' - f'\|_2^2 \leq 0.82^{s_1} \cdot (4m) + 2^{4(s_1 \cdot \log m)^d \log m} \cdot \text{tail}(m^3, d + 3, s_2)$ , and
4.  $f'(x) = 0$  whenever  $F'(x) = 0$ .

## 15:24 Tight Bounds on the Fourier Spectrum of $\text{AC}^0$

**Proof.** The first two properties follow from Lemma 43 directly, since

$$\Pr_{\mu}[\mathcal{E}_{\nu} = 1], \Pr_{U_n}[\mathcal{E}_{\nu} = 1] \leq 2 \cdot \Pr_{\nu}[\mathcal{E}_{\nu} = 1] \leq 2 \cdot 0.82^{s_1} m .$$

Let  $f$  be the degree  $(s_1 \cdot \log m)^d$  approximation of  $F$  from Lemma 43. By Proposition 44,

$$\|f\|_{\infty} < (2m)^{(s_1 \cdot \log m)^d - 2} < 2^{2(s_1 \log m)^d \log(m) - 2} .$$

Let  $\tilde{\mathcal{E}}_{\nu}$  be the truncated Fourier expansion of  $\mathcal{E}_{\nu}$  of degree  $s_2$ . We have

$$\|\mathcal{E}_{\nu} - \tilde{\mathcal{E}}_{\nu}\|_2^2 \leq \text{tail}(m^3, d + 3, s_2) .$$

Let

$$f' := f \cdot (1 - \tilde{\mathcal{E}}_{\nu})$$

Then  $f' = 0$  whenever  $F' = 0$  (since  $(F' = 0) \implies (\mathcal{E}_{\nu} = 0, F = 0) \implies (f = 0) \implies (f' = 0)$ ). It remains to estimate  $\|F' - f'\|_2^2$ :

$$\begin{aligned} \|F' - f'\|_2^2 &\leq 2 \cdot \|F' - f \cdot (1 - \mathcal{E}_{\nu})\|_2^2 + 2 \cdot \|f \cdot (1 - \mathcal{E}_{\nu}) - f'\|_2^2 \\ &= 2 \cdot \|\mathcal{E}_{\nu}\|_2^2 + 2 \cdot \|f \cdot (\mathcal{E}_{\nu} - \tilde{\mathcal{E}}_{\nu})\|_2^2 \\ &\leq 2 \cdot \Pr[\mathcal{E}_{\nu} = 1] + 2 \cdot \|f\|_{\infty}^2 \cdot \|\mathcal{E}_{\nu} - \tilde{\mathcal{E}}_{\nu}\|_2^2 \\ &\leq 0.82^{s_1} \cdot (4m) + 2^{4(s_1 \cdot \log m)^d \log m} \cdot \text{tail}(m^3, d + 3, s_2), \end{aligned}$$

which completes the proof.  $\blacktriangleleft$

**► Theorem 46** ([7, Rephrasing of Main Theorem]). *Let  $s_1, s_2 \geq \log m$  be any parameters. Let  $F$  be a Boolean function computed by a circuit of depth  $d$  and size  $m$ . Let  $\mu$  be an  $r$ -independent distribution where*

$$r = r(s_1, s_2, d) = 2((s_1 \cdot \log m)^d + s_2)$$

then

$$|\mathbf{E}_{\mu}[F] - E[F]| \leq \varepsilon(s_1, s_2, d),$$

where  $\varepsilon(s_1, s_2, d) = 0.82^{s_1} \cdot (6m) + 2^{4(s_1 \cdot \log m)^d \log m} \cdot \text{tail}(m^3, d + 3, s_2)$

**Proof of Theorem 46.** Denote by  $\varepsilon_1 := 0.82^{s_1} \cdot (2m)$  and

$$\varepsilon_2 := 0.82^{s_1} \cdot (4m) + 2^{4(s_1 \cdot \log m)^d \log m} \cdot \text{tail}(m^3, d + 3, s_2) .$$

Applying Lemma 45 with parameters  $s_1$  and  $s_2$  gives

$$\|F' - f'\|_2^2 \leq \varepsilon_2 .$$

Now take  $f'_{\ell} := 1 - (1 - f')^2$ . Then  $f'_{\ell} \leq 1$  and  $f'_{\ell} = 0$  whenever  $F' = 0$ , hence  $f'_{\ell} \leq F'$ . To estimate  $\mathbf{E}[F'(x) - f'_{\ell}(x)]$  we note that  $F'(x) - f'_{\ell}(x)$  equals 0 whenever  $F' = 0$ , and is equal to

$$F'(x) - f'_{\ell}(x) = (1 - f'(x))^2 = (F'(x) - f'(x))^2$$

whenever  $F' = 1$ . We get

$$\mathbf{E}[F'(x) - f'_\ell(x)] \leq \|F' - f'_\ell\|_2^2 \leq \varepsilon_2.$$

In addition,  $\deg(f'_\ell(x)) \leq 2(s_2 + (s_1 \cdot \log m)^d)$ .

To finish the proof, if  $\mu$  is a  $(2 \cdot (s_2 + (s_1 \cdot \log m)^d))$ -wise independent distribution then

$$\begin{aligned} \mathbf{E}_\mu[F(x)] &\geq \mathbf{E}_\mu[F'(x)] - \varepsilon_1 \geq \mathbf{E}_\mu[f'_\ell(x)] - \varepsilon_1 =^* \mathbf{E}[f'_\ell(x)] - \varepsilon_1 \\ &= \mathbf{E}[F'(x)] - \mathbf{E}[F'(x) - f'_\ell(x)] - \varepsilon_1 \geq \mathbf{E}[F'(x)] - \varepsilon_2 - \varepsilon_1 \geq \mathbf{E}[F(x)] - \varepsilon_2 - \varepsilon_1 \end{aligned}$$

where we used in  $*$  the fact that  $\deg(f'_\ell) \leq 2(s_2 + (s_1 \cdot \log m)^d)$  and  $\mu$  is  $\deg(f'_\ell)$ -wise independent. In a similar way, one can show  $\mathbf{E}_\mu[F(x)] \leq \mathbf{E}[F(x)] + \varepsilon_1 + \varepsilon_2$ . Combining both cases we get

$$|\mathbf{E}_\mu[F] - \mathbf{E}[F]| \leq \varepsilon_1 + \varepsilon_2 = \varepsilon(s_1, s_2, d). \quad \blacktriangleleft$$

## C Improving the Analysis of De, Etesami, Trevisan and Tulsiani

De et al. [9] proved that any  $\varepsilon$ -biased distribution  $\delta$ -fools depth-2 circuits (**DNFs** or **CNFs**) of size  $m$ , for some  $\varepsilon = \varepsilon(\delta, m)$ . In fact, their work shows that generators of  $\varepsilon$ -biased distributions are the best known pseudorandom generators fooling depth-2 circuits. We are able to improve their analysis slightly, getting an optimal dependence between  $\varepsilon$  and  $\delta$ .

Some notation is needed first. Throughout this section (and the next), we shall think of Boolean functions as functions  $f : \{0, 1\}^n \rightarrow \mathbb{R}$  (as opposed to  $f : \{-1, 1\}^n \rightarrow \mathbb{R}$ ). We can identify each function  $f : \{0, 1\}^n \rightarrow \mathbb{R}$  with a function  $\tilde{f} : \{-1, 1\}^n \rightarrow \mathbb{R}$  by  $\tilde{f}(y_1, \dots, y_n) = f(\frac{1-y_1}{2}, \dots, \frac{1-y_n}{2})$  or equivalently  $f(x_1, \dots, x_n) = \tilde{f}((-1)^{x_1}, \dots, (-1)^{x_n})$ . When talking about the Fourier expansion of  $f$ , we mean the Fourier expansion of  $\tilde{f}$  as defined in Section 2. In this notation,  $f(x) = \sum_{S \subseteq [n]} \hat{f}(S) \cdot (-1)^{\sum_{i \in S} x_i}$ .

Next, we discuss **DNFs** and **CNFs**. Disjunctive normal forms (**DNFs**) are expressions of the form  $F(x) = \bigvee_{i=1}^m t_i(x)$  where each term  $t_i(x)$  is an AND of some literals from  $x_1, \dots, x_n, \neg x_1, \dots, \neg x_n$ . If any term in  $F$  is an AND of at most  $w$  literals, then we say that  $F$  is of width  $w$ , and we call  $F$  a  $w$ -**DNF**. Similarly conjunctive normal forms (**CNFs**) are expressions of the form  $F(x) = \bigwedge_{i=1}^m c_i(x)$  where each clause  $c_i$  is an OR of some literals. We define  $w$ -**CNFs** similarly to  $w$ -**DNFs**. The size of a **DNF** (**CNF**, resp.) is the number of terms (clauses, resp.) in it, i.e.,  $m$  in the examples above.

Recall the definition of the spectral norm of a Boolean function  $L_1(f) = \sum_S |\hat{f}(S)|$  and denote by  $L_1^*(f) = \sum_{S \neq \emptyset} |\hat{f}(S)|$ . We denote by  $U_n$  the uniform distribution over  $\{0, 1\}^n$ .

We cite a proposition and two lemmata from the work of De et al. [9].

► **Proposition 47** ([9, Prop. 2.6]). *Suppose  $f, f_\ell, f_u : \{0, 1\}^n \rightarrow \mathbb{R}$  are three functions such that for every  $x \in \{0, 1\}^n$  we have  $f_\ell(x) \leq f(x) \leq f_u(x)$ . Furthermore, assume  $\mathbf{E}_{x \sim U_n}[f(x) - f_\ell(x)] \leq \delta$  and  $\mathbf{E}_{x \sim U_n}[f_u(x) - f(x)] \leq \delta$ . Let  $l = \max(L_1^*(f_\ell), L_1^*(f_u))$ . Then, any  $\varepsilon$ -biased probability distribution  $(\delta + \varepsilon l)$ -fools  $f$ .*

► **Lemma 48** ([9, Lemma 4.3]). *Let  $f : \{0, 1\}^n \rightarrow \{0, 1\}$  be a **DNF** with  $m$  terms and  $g : \{0, 1\}^n \rightarrow \mathbb{R}$  be such that:  $L_1(g) \leq l_1$ ,  $\|f - g\|_2^2 \leq \varepsilon_1$  and  $g(x) = 0$  whenever  $f(x) = 0$ . Then, we can get  $f_\ell, f_u : \{0, 1\}^n \rightarrow \mathbb{R}$  such that*

- $\forall x, f_\ell(x) \leq f(x) \leq f_u(x)$
- $\mathbf{E}_{x \sim U_n}[f_u(x) - f(x)] \leq m \cdot \varepsilon_1$  and  $\mathbf{E}_{x \sim U_n}[f(x) - f_\ell(x)] \leq m \cdot \varepsilon_1$ .
- $L_1(f_\ell), L_1(f_u) \leq (m + 1)(l_1 + 1)^2 + 1$ .

► **Lemma 49** ([9, Lemma 4.4]). *Let  $f : \{0, 1\}^n \rightarrow \{0, 1\}$  be a **DNF** with  $m$  terms and width- $w$ . Suppose for every **DNF** with at most  $m$  terms and width- $w$ ,  $f_1$ , there is a function  $g_1 : \{0, 1\}^n \rightarrow \mathbb{R}$  such that:  $L_1(g_1) \leq l_2$  and  $\|f_1 - g_1\|_2^2 \leq \varepsilon_2$ . Then, we can get  $g : \{0, 1\}^n \rightarrow \mathbb{R}$  such that  $L_1(g) \leq m \cdot (l_2 + 1)$ ,  $\|f - g\|_2^2 \leq m^2 \cdot \varepsilon_2$  and  $g(x) = 0$  whenever  $f(x) = 0$ .*

De et al. [9] used Lemma 49 with a bound on the width of the approximated **DNF**. We will use Lemma 49 without any assumption on the width.

The following is a corollary of Thm. 37.

► **Corollary 50.** *Let  $f : \{0, 1\}^n \rightarrow \{0, 1\}$  be a **DNF** of size  $m$  and  $\varepsilon_2 > 0$ . Then, there is a function  $g_1 : \{0, 1\}^n \rightarrow \mathbb{R}$  such that  $\mathbf{E}[(f - g_1)^2] \leq \varepsilon_2$  and  $L_1(g_1) = 2^{O(\log m \cdot \log \log m \cdot \log(1/\varepsilon_2))}$ .*

**Proof.** According to Thm. 37, there is a set  $\mathcal{F}$  of coefficients such that  $|\mathcal{F}| \leq 2^{O(\log m \cdot \log \log m \cdot \log(1/\varepsilon_2))}$  and  $\sum_{S \notin \mathcal{F}} \hat{f}(S)^2 \leq \varepsilon_2$ . Hence,  $g_1(x) = \sum_{S \in \mathcal{F}} \hat{f}(S) \cdot (-1)^{\sum_{i \in S} x_i}$  is an approximation of  $f$  with

$$\mathbf{E}_x[(f(x) - g_1(x))^2] = \sum_{S \notin \mathcal{F}} \hat{f}(S)^2 \leq \varepsilon_2.$$

where we used Parseval's identity. Since each Fourier coefficient is at most 1 in absolute value  $L_1(g_1) = \sum_{S \in \mathcal{F}} |\hat{f}(S)| \leq |\mathcal{F}|$ , which completes the proof. ◀

The following theorem is our refinement of [9, Thm. 4.1].

► **Theorem 51.** *Let  $f$  be a **DNF** formula with  $m$  terms. Then,  $f$  is  $\delta$ -fooled by any  $\varepsilon$ -biased distribution where  $\varepsilon = 2^{O(\log m \cdot \log(m/\delta) \cdot \log \log m)}$ .*

**Proof.** Set  $\varepsilon_2 = \delta/2m^3$  and  $\varepsilon_1 = \delta/2m$ . By applying Corollary 50 for every **DNF** formula of size  $m$ ,  $f_1$ , there exists a function  $g_1 : \{0, 1\}^n \rightarrow \mathbb{R}$  such that

- $\mathbf{E}[(f_1 - g_1)^2] \leq \varepsilon_2$
- $L_1(g_1) \leq 2^{O(\log m \cdot \log \log m \cdot \log(1/\varepsilon_2))} = 2^{O(\log m \cdot \log \log m \cdot \log(m/\delta))}$

We apply Lemma 49 with width  $n$  (this is a trivial choice of width, since all **DNFs** on  $n$  variables are of width at most  $n$  without loss of generality),  $\varepsilon_2 = \delta/2m^3$  and  $l_2 = 2^{O(\log m \cdot \log \log m \cdot \log(m/\delta))}$ . Then, we get the existence of a function  $g : \{0, 1\}^n \rightarrow \mathbb{R}$  such that  $g(x) = 0$  whenever  $f(x) = 0$  and  $\mathbf{E}[(g - f)^2] \leq m^2 \varepsilon_2 = \delta/2m$ . and  $L_1(g) \leq (l_2 + 1) \cdot m = 2^{O(\log m \cdot \log \log m \cdot \log(m/\delta))}$ . Then, we apply Lemma 48 with  $g$ ,  $\varepsilon_1 = \delta/2m$  and  $l_1 = L_1(g) = 2^{O(\log m \cdot \log \log m \cdot \log(m/\delta))}$  to get a sandwiching approximation of  $f$  by  $f_\ell$  and  $f_u$  such that

- $\forall x : f_\ell(x) \leq f(x) \leq f_u(x)$
- $\mathbf{E}_{x \sim U_n}[f_u(x) - f(x)] \leq m \cdot \varepsilon_1 = \delta/2$  and  $\mathbf{E}_{x \sim U_n}[f(x) - f_\ell(x)] \leq m \cdot \varepsilon_1 = \delta/2$ .
- $L_1(f_u), L_1(f_\ell) \leq (l_1 + 1)^2 \cdot (m + 1) + 1 = 2^{O(\log m \cdot \log \log m \cdot \log(m/\delta))}$ .

Denote by  $l = (l_1 + 1) \cdot (m + 1) + 1$ . Applying Prop. 47, we get that any  $\varepsilon = \delta/(2l) = 2^{-O(\log m \cdot \log \log m \cdot \log(m/\delta))}$  biased distribution  $\gamma$ -fools  $f$ , where  $\gamma = \delta/2 + \varepsilon \cdot l \leq \delta$ . ◀

It is well-known from the works of [26, 3] that  $\varepsilon$ -biased distributions on  $n$  bits may be sampled using a  $O(\log n + \log(1/\varepsilon))$ -seed length, which gives the following corollary.

► **Theorem 52.** *There exists a polynomial time pseudorandom generator  $\mathcal{G}$  of seed length  $O(\log n + \log m \cdot \log \log m \cdot \log(m/\delta))$  that  $\delta$ -fools all **DNFs** of size  $m$  on  $n$  variables.*

Note that by de Morgan laws every **DNF** of size  $m$  is the negation of a **CNF** of size  $m$ , and vice versa. Hence, any pseudorandom generator that fools **DNFs** also fools **CNFs**.

## D Improving the Generator of Trevisan and Xue

In this section, we revisit the pseudorandom generator of Trevisan and Xue [35] that  $\varepsilon$ -fools  $\mathbf{AC}^0$  circuits of size  $M$  and depth  $d$ . We improve its seed-length from  $O(\log^{d+3}(M/\varepsilon) \cdot \log(n/\varepsilon))$  to  $O(\log^{d+1}(M/\varepsilon) \cdot \log n)$  by two observations in addition to the improved analysis of the generator of De et al. (see Thm. 52).

We start by explaining the sampling process of Trevisan and Xue's generator at a high-level. The generator applies  $O(\log^{d-1}(M/\varepsilon) \cdot \log(n/\varepsilon))$  pseudorandom restrictions iteratively, where each pseudorandom restriction fixes each variable (that wasn't already fixed) with probability  $\Theta(1/\log^{d-1}(M/\varepsilon))$ . The seed length required per step is  $\tilde{O}(\log^4(M/\varepsilon))$ . Each pseudo-random restriction consists of a pseudorandom process that selects which variables to fix, in addition to a pseudorandom process that selects the values for these variables. The heart of Trevisan and Xue's analysis is a proof that the selection of which variables to fix can be done by sampling recursively  $d$  times (one per depth) from any distribution that fools CNFs with appropriate parameters. This is done by proving that any distribution that fools CNFs, also fools Håstad's switching lemma [14] (see Lemma 53 below).

Our improvement from seed-length  $\tilde{O}(\log^{d+3}(M/\varepsilon) \cdot \log(n/\varepsilon))$  to  $\tilde{O}(\log^{d+1}(M/\varepsilon) \cdot \log n)$  is a combination of three improvements:

- We get a factor of  $\log(M/\varepsilon)$  improvement via a better analysis of the pseudorandom generator of De et al. [9] (see Section C). We get a better dependency on the error parameter  $\varepsilon_0$  in Thm. 52, compared to the corresponding theorem of [9]. Since Trevisan and Xue use Thm. 52 with error parameter  $\varepsilon_0 = 1/2^{\Theta(\log^2(M/\varepsilon))}$  that is much smaller than any polynomial in  $\varepsilon/M$ , this improvement is effective.
- We get a factor of  $\log(M/\varepsilon)$  improvement by applying the switching lemma for one less step. We show that with high probability the circuit collapses to a depth-2 circuit instead of collapsing to a bounded depth decision tree. Since we are able to fool depth-2 circuits by Thm. 52, this is enough.<sup>8</sup>
- We replace a factor of  $\log(n/\varepsilon)$  by a factor of  $\log(n)$  by noting that one can continue restricting variables until less than  $O(\log(1/\varepsilon))$  variables are alive, and then fix the remaining variables using a  $O(\log(1/\varepsilon))$ -wise independent distribution. In the original analysis, one waited until all variables were fixed.

In the rest of the section, we will use the following notation (as suggested by Trevisan and Xue [35]). A restriction may be defined (not uniquely) by two binary strings of length  $n$ :  $\theta \in \{*, \square\}^n$  and  $\beta \in \{0, 1\}^n$ , where for  $i \in [n]$ ,

$$\rho(i) = \begin{cases} \beta(i), & \theta(i) = \square \\ *, & \theta(i) = * \end{cases}.$$

We shall identify a string  $w \in \{0, 1\}^{n(q+1)}$  with a restriction as follows. We partition  $w$  to  $(l, r)$  where  $l$  consists of the first  $qn$  bits of  $w$ , and  $r$  consists of the last  $n$  bits of  $w$ . We further partition  $l \in \{0, 1\}^{nq}$  to  $n$  blocks of  $q$  consecutive bits each. For block  $i \in [n]$ , we take  $\theta(i) = *$  iff all the  $q$  bits in the block equal 1. We take  $\beta = r$  and yield the restriction defined by  $(\theta, \beta)$ .

<sup>8</sup> To get another  $\tilde{O}(\log(M/\varepsilon))$  improvement it is enough to construct PRGs for depth-3 circuits with seed-length  $\tilde{O}(\log^3(M/\varepsilon))$ . Then, one can stop one step sooner (i.e. when reaching depth-3) and apply the PRG for depth-3 on the remaining circuit.

## 15:28 Tight Bounds on the Fourier Spectrum of $\text{AC}^0$

If  $D$  is a distribution over  $\{0, 1\}^{(q+1)n}$ , then  $(\theta, \beta) \sim D$  means that we sample  $w \sim D$  as a string of length  $(q+1)n$  and use the aforementioned identification to get  $\theta \in \{*, \square\}^n$  and  $\beta \in \{0, 1\}^n$ . Note that sampling  $w \in \{0, 1\}^{n \cdot (q+1)}$  uniformly at random yields a restriction  $\rho = (\theta, \beta)$  distributed according to  $\mathcal{R}_p$  for  $p = 2^{-q}$ .

► **Lemma 53** ([35, Lemma 7]). *Let  $F$  be a CNF of size  $M$  and width  $t$  over  $n$  variables,  $p_0 = 2^{-q_0}$  where  $q_0 \in \mathbb{N}$ , and  $D$  be a distribution over  $\{0, 1\}^{(q_0+1)n}$  that  $\varepsilon_0$ -fools all CNFs of size at most  $M \cdot 2^{t \cdot (q_0+1)}$ . Then,*

$$\Pr_{(\theta, \beta) \sim D} [\text{DT}(F|_{\theta, \beta}) > s] \leq 2^{s+t+1} \cdot (5p_0t)^s + \varepsilon_0 \cdot 2^{(s+1) \cdot (2t + \log M)},$$

where  $\text{DT}(f)$  denotes the depth of the smallest decision tree computing a function  $f$ .<sup>9</sup>

The following is a slight generalization of [35, Fact 9].

► **Fact 54** ([35, Fact 9]). *Let  $D_1$  be a distribution over  $\{0, 1\}^{n_1}$  that  $\varepsilon_1$ -fools CNFs of size  $m$  on  $n_1$  variables. Let  $D_2$  be a distribution over  $\{0, 1\}^{n_2}$  that  $\varepsilon_2$ -fools CNFs of size  $m$  on  $n_2$  variables. Let  $D_1 \otimes D_2$  be the distribution over  $\{0, 1\}^{n_1+n_2}$  sampled by concatenating independent samples from  $D_1$  and  $D_2$ . Then,  $D_1 \otimes D_2$  is a distribution that  $(\varepsilon_1 + \varepsilon_2)$ -fools CNFs of size  $m$  on  $n_1 + n_2$  variables.*

**Proof.** Let  $F(X, Y)$  be a CNF of size  $m$  on  $n_1 + n_2$  variables, where  $X$  consists of the first  $n_1$  variables and  $Y$  consists of the last  $n_2$  variables. We have

$$\mathbf{E}_{x \sim U_{n_1}, y \sim U_{n_2}} [F(x, y)] = \mathbf{E}_{x \sim U_{n_1}} [\mathbf{E}_{y \sim U_{n_2}} [F_x(y)]]$$

where  $F_x(\cdot)$  is the CNF  $F$  when the variables  $X$  are fixed to  $x$ . Note that  $F_x(\cdot)$  is in itself a CNF of size at most  $m$  on  $n_2$  variables. By assumption, for all values of  $x$ ,

$$\mathbf{E}_{y \sim U_{n_2}} [F_x(y)] = \mathbf{E}_{y \sim D_2} [F_x(y)] \pm \varepsilon_2. \quad (9)$$

Similarly for any fixed assignment  $Y = y$ , we have

$$\mathbf{E}_{x \sim U_{n_1}} [F(x, y)] = \mathbf{E}_{x \sim D_1} [F(x, y)] \pm \varepsilon_1. \quad (10)$$

Combining Eqs. (9) and (10) gives

$$\begin{aligned} \mathbf{E}_{x \sim U_{n_1}, y \sim U_{n_2}} [F(x, y)] &= \mathbf{E}_{x \sim U_{n_1}} \left[ \mathbf{E}_{y \sim D_2} [F_x(y)] \pm \varepsilon_2 \right] \\ &= \mathbf{E}_{y \sim D_2} \left[ \mathbf{E}_{x \sim U_{n_1}} [F(x, y)] \pm \varepsilon_2 \right] \\ &= \mathbf{E}_{y \sim D_2} \left[ \mathbf{E}_{x \sim D_1} [F(x, y)] \pm \varepsilon_1 \pm \varepsilon_2 \right] \\ &= \mathbf{E}_{x \sim D_1, y \sim D_2} [F(x, y)] \pm (\varepsilon_1 + \varepsilon_2). \quad \blacktriangleleft \end{aligned}$$

By induction, Fact 54 implies the following corollary.

<sup>9</sup> Actually, Trevisan and Xue show the stronger result where  $\text{DT}(f)$  is replaced by the depth of the canonical decision tree for  $f$  (see Section 7 for its definition). However, we do not benefit from this strengthening.

► **Corollary 55.** *Let  $D$  be a distribution over  $\{0, 1\}^n$  that  $\varepsilon$ -fools CNFs of size  $m$ . Let  $t \in \mathbb{N}$ , and  $D^{\otimes t}$  be the distribution over  $\{0, 1\}^{n \cdot t}$  sampled by concatenating  $t$  independent samples from  $D$ . Then,  $D^{\otimes t}$  is a distribution that  $(\varepsilon \cdot t)$ -fools CNFs of size  $m$  on  $n \cdot t$  variables.*

In the following theorems we shall assume that the circuit size  $M$  is larger than the length of the input  $n$ .

► **Theorem 56** ([35, Thm. 11, “Derandomized Switching Lemma for  $\text{AC}^0$ ”, restated]). *Let  $C$  be circuit on  $n$  variables with size  $M$ , depth  $d$  and a top OR-gate. Let  $p = 2^{-q}$ , where  $q \in \mathbb{N}$ , and  $s \in \mathbb{N}$  be some positive parameter. Assume that there exists a pseudorandom generator  $\mathcal{G}$  with seed length  $r$  that  $\varepsilon_0$ -fools CNFs of size  $M \cdot 2^s \cdot 2^{s \cdot (q+1)}$ . Then, there exists a pseudorandom selection generator  $\mathcal{G}_0$  of seed length  $(d-1) \cdot r$  such that:*

- $\Pr_{\theta \sim \mathcal{G}_0, \beta \sim \mathcal{U}} [F|_{\theta, \beta} \text{ is not an } s\text{-DNF of size } \leq M \cdot 2^s]$   
 $\leq M \cdot (2^{2s+1} \cdot \max\{(5ps)^s, (5/64)^s\} + \varepsilon_0 \cdot 2^{(s+1) \cdot (3s + \log M)})$ .
- For each set of variables  $T \subseteq [n]$ , the probability that all variables in  $T$  are fixed is at most  $(1 - p^{d-2}/64)^{|T|} + \varepsilon_0 \cdot (d-1)$ .

**Proof.** We shall start by adding a dummy layer next to the inputs that transforms the circuit  $C$  into a circuit  $C'$  of size at most  $M \cdot n$ , depth  $d+1$  and bottom fan-in 1. We construct  $\mathcal{G}_0$  by running  $(d-1)$  iterative pseudorandom selections, using the generator of [9] in each iteration. By Fact 54, the pair  $(\theta, \beta)$  obtained by sampling  $\theta \sim \mathcal{G}$  and  $\beta \in \{0, 1\}^n$  uniformly at random,  $\varepsilon_0$ -fools CNFs of size  $M \cdot 2^s \cdot 2^{s \cdot (q+1)}$ . We denote by  $M_1, \dots, M_d$  the number of gates in the original circuit  $C$  at distance  $1, \dots, d$  from the inputs, respectively.

**The first iteration.** For the first iteration of Lemma 53, we pick  $p_0 = 1/64$  and  $t = 1$ . The probability that under the pseudorandom restriction, one of the gates at distance 2 from the inputs cannot be computed by a decision tree of depth  $s$  is at most

$$M_1 \cdot \left( 2^{s+1+1} \cdot (5/64)^s + \varepsilon_0 \cdot 2^{(s+1)(2+\log M)} \right).$$

In the complement event, we may express each gate at distance 2 from the inputs both as an  $s$ -DNF and as an  $s$ -CNF, so we can collapse this layer with the layer above it. This simplification yields a circuit of depth  $d$ , fan-in  $s$  and does not introduce new gates at distance 2 or more from the inputs. The number of gates at distance 1 from the inputs is at most  $M \cdot 2^s$ , since each depth- $s$  decision tree is an  $s$ -DNF of size at most  $2^s$  (and similarly an  $s$ -CNF of size at most  $2^s$ ).

**The other  $d-2$  iterations.** At iteration  $i = 2, \dots, d-1$ , we apply Lemma 53 with  $t = s$  and  $p_0 = p$ . We get that under the pseudorandom restriction, the probability that there exists a gate at distance 2 from the inputs that cannot be computed by a decision tree of depth  $s$  is at most

$$M_i \cdot \left( 2^{s+s+1} \cdot (5ps)^s + \varepsilon_0 \cdot 2^{(s+1)(2s+\log(M \cdot 2^s))} \right).$$

We are using the fact that each gate at distance 2 from the inputs computes a CNF/DNF of size at most  $M \cdot 2^s$  and bottom fan-in  $s$ , an invariant that is preserved during the iterative process. Again, if a gate is computed by a decision tree of depth  $s$  then it is also computed by an  $s$ -CNF and by an  $s$ -DNF of size at most  $2^s$ , and we may collapse the layers at distances 2 and 3 from the inputs.

15:30 **Tight Bounds on the Fourier Spectrum of AC<sup>0</sup>**

Overall, after  $(d - 1)$ -iterations, with probability at least

$$1 - M \cdot \left( 2^{s+s+1} \cdot \max\{(5ps)^s, (5/64)^s\} + \varepsilon_0 \cdot 2^{(s+1)(3s+\log M)} \right),$$

all “switchings” were successful and we got a circuit of depth-2, size at most  $M \cdot 2^s$ , bottom fan-in  $s$  and a top OR gate, i.e. we got an  $s$ -DNF.

As for the second item of the theorem, observe that  $\theta$  is selected by sampling  $d - 1$  binary strings from  $\mathcal{G}$ : one string  $w_1$  of length  $n \cdot \log_2(64)$  (consisting of  $n$  blocks of  $\log_2(64)$  bits each) and  $(d - 2)$  strings,  $w_2, \dots, w_{d-1}$ , of length  $n \cdot q$  (consisting of  $n$  blocks of  $q$  bits each). We denote the concatenation of these  $d - 1$  strings by  $w$ . The  $i$ -th bit in  $\theta$  is fixed (i.e.  $\theta_i = \square$ ) iff the  $i$ -th block in one of the  $d - 1$  strings contains a zero. Thus, the event  $\theta(i) = \square$  may be expressed as an OR of  $6 + (d - 2)q$  literals over  $w$ . The event that a set of  $T$  variables is fixed may be expressed as a CNF of size  $|T| \leq n$  in the bits of  $w$ . By Corollary 55, the distribution of  $w$  is  $\varepsilon_0 \cdot (d - 1)$ -pseudorandom for CNFs of size at most  $M \cdot 2^s \cdot 2^{s(q+1)}$  and in particular to CNFs of size at most  $n$ . Thus,

$$\begin{aligned} \Pr_{w \text{ pseudo-random}} [T \text{ is fixed under } w] &\leq \Pr_{w \text{ random}} [T \text{ is fixed under } w] + \varepsilon_0 \cdot (d - 1) \\ &= (1 - p^{d-2}/64)^{|T|} + \varepsilon_0 \cdot (d - 1). \quad \blacktriangleleft \end{aligned}$$

► **Theorem 57** ([35, Theorem 12, restated slightly]). *Let  $C$  be a size  $M$ , depth  $d$  circuit, and  $\varepsilon > 0$ . Then, there exists a pseudorandom generator  $\mathcal{G}_1$  of seed length  $\tilde{O}(\log^3(M/\varepsilon))$  such that:*

- $|\Pr_{\rho \sim \mathcal{G}_1, x \sim U_n} [C_\rho(x) = 1] - \Pr_{y \sim U_n} [C(y) = 1]| < \varepsilon$ .
- Let  $p$  be the largest power of  $1/2$  less than  $1/(64 \log(8M/\varepsilon))$ . Then, each set of variables  $T \subseteq [n]$  has probability at most  $(1 - p^{d-2}/64)^{|T|} + \varepsilon_0 \cdot (d - 1)$  of being unassigned by  $\rho$ .

**Proof.** We initiate the generator from Thm. 56 based on the generator from Thm. 52. We choose parameters so that the bound we get from Thm. 56 is at most  $\varepsilon/2$ . Choosing  $s$  to be a power of 2 between  $\log(8M/\varepsilon)$  to  $2 \log(8M/\varepsilon)$ ,  $p = 1/64s$  and  $\varepsilon_0 = 2^{-9s^2}$  guarantees that

$$M \cdot (2^{2s+1} \cdot \max\{(5ps)^s, (5/64)^s\} + \varepsilon_0 \cdot 2^{(s+1) \cdot (3s+\log M)}) \leq \varepsilon/2.$$

The choice also guarantees that  $\varepsilon_0 \leq \varepsilon/2$ . In order to apply Thm. 56 with these parameters, the generator  $\mathcal{G}$  in Thm. 52 should  $\varepsilon_0$ -fool circuits of size  $M' = M \cdot 2^{(q+2)s} = 2^{O(\log(M/\varepsilon) \log \log(M/\varepsilon))}$ . Theorem 52 guarantees that seed-length  $r = \tilde{O}(\log(M')) \cdot \log(M'/\varepsilon_0) = \tilde{O}(\log^3(M/\varepsilon))$  is enough.

The generator in Thm. 56,  $\mathcal{G}_0$ , selects a set of coordinates  $J = \{i \in [n] : \theta(i) = *\}$ . Thm. 56 guarantees that with probability at least  $(1 - \varepsilon/2)$  over the choice of  $J$  and the restriction of  $J^c$  by random bits,  $C$  reduces to an  $s$ -DNF of size at most  $M \cdot 2^s$ . We then assign values to the variables indexed by  $J$  according to De et al. generator,  $\mathcal{G}$ . Overall, we need seed-length  $(d - 1) \cdot r + r = dr$ , where the first term comes from sampling from  $\mathcal{G}_0$  and the second from sampling according to  $\mathcal{G}$ .

For any fixed choice of  $\theta$  we have:

$$\Pr_{y \sim U_n} [C(y) = 1] = \Pr_{x \sim U_J, z \sim U_{J^c}} [C(x, z) = 1] = \mathbf{E}_z \left[ \Pr_x [C(x, z) = 1] \right].$$

Hence also for  $\mathcal{G}_0$  which is a distribution over selections  $\theta$  the following holds

$$\Pr_{y \sim U_n} [C(y) = 1] = \mathbf{E}_\theta \mathbf{E}_z \left[ \Pr_x [C(x, z) = 1] \right]$$

For choices  $(\theta, z)$  such that  $C_z(x) := C(x, z)$  is an  $s$ -DNF of size at most  $M \cdot 2^s$ , we have  $\Pr_{x \sim U_J}[C(x, z) = 1] = \Pr_{x \sim \mathcal{G}}[C(x, z) = 1] \pm \varepsilon_0$ . In the case where  $C_z(x)$  is not an  $s$ -DNF of size  $M \cdot 2^s$  we trivially have  $\Pr_{x \sim U_J}[C(x, z) = 1] = \Pr_{x \sim \mathcal{G}}[C(x, z) = 1] \pm 1$ . However, this is a rare event that happens with probability at most  $\varepsilon/2$ . Overall, we have

$$\Pr_{y \sim U_n}[C(y) = 1] = \mathbf{E}_{\theta} \mathbf{E}_z [\Pr_{x \sim U_J}[C(x, z) = 1]] = \mathbf{E}_{\theta} \mathbf{E}_z [\Pr_{x \sim \mathcal{G}}[C(x, z) = 1]] \pm (\varepsilon_0 + \varepsilon/2).$$

which completes the proof of the first item as  $\varepsilon_0 \leq \varepsilon/2$ .

Note that the generator  $\mathcal{G}_1$  selects  $J$  and assigns values to the variables in  $J$ . It does not assign any of the variables in  $J^c$ . In this way, Trevisan and Xue change roles between the fixed and alive parts of the restriction: starting with pseudorandom restriction where  $J^c$  is fixed randomly and  $J$  is kept alive, they end up with a pseudorandom restriction where  $J$  is fixed pseudorandomly and  $J^c$  is kept alive.

The second item follows by observing that a set of variables is fixed in Thm. 56 iff it is unassigned here.  $\blacktriangleleft$

**► Theorem 58** ([35, Theorem 13, improved]). *For every  $M, d, n, \varepsilon$  there is a polynomial time computable  $\varepsilon$ -pseudorandom generator for circuits of size  $M$  and depth  $d$  on  $n$  variables, whose seed length is  $\tilde{O}(\log^{d+1}(M/\varepsilon) \cdot \log n)$ .*

**Proof.** If  $d \leq 2$  we apply Thm. 52. Otherwise, we may assume  $d \geq 3$ . As in Thm. 57, let  $p$  be the largest power of  $1/2$  which is smaller than  $1/(64 \log(8M/\varepsilon))$ . Let  $p' = p^{d-2}/64$ . The theorem follows by applying  $R = 3 \ln(n)/p'$  independent random restrictions from  $\mathcal{G}_1$ , each with parameter  $\varepsilon/2R$ . Let  $t = \log(2/\varepsilon)$ , and let  $T \subseteq [n]$  be a set of size  $t$ . The probability  $T$  remains totally unfixed after  $R$  iterations is at most

$$((1 - p')^t + \varepsilon_0 \cdot (d - 1))^{3 \ln(n)/p'}$$

where recall that  $\varepsilon_0 = 2^{-\Omega(\log^2(M/\varepsilon))}$ . We have  $(1 - p')^t > 1 - p't \geq 1 - \frac{\log(2/\varepsilon)}{64 \log(8/\varepsilon)} > 1/2$ , so

$$(1 - p')^t + \varepsilon_0 \cdot (d - 1) \leq (1 - p')^t \cdot (1 + 2\varepsilon_0 \cdot (d - 1)),$$

and we get

$$\begin{aligned} ((1 - p')^t + \varepsilon_0 \cdot (d - 1))^{3 \ln(n)/p'} &< ((1 - p')^t \cdot (1 + 2\varepsilon_0 \cdot (d - 1)))^{3 \ln(n)/p'} \\ &\leq e^{(-p't) \cdot 3 \ln(n)/p'} \cdot e^{2\varepsilon_0 \cdot (d-1) \cdot 3 \ln(n)/p'} \quad (1 + x \leq e^x) \\ &= n^{-3t} \cdot e^{o(1)} = O(n^{-3t}). \end{aligned}$$

As there are only at most  $n^t$  sets  $T$  of size  $t$ , applying union bound, with probability at most  $O(n^{-2t}) < \varepsilon/2$  there exists a set of size  $t$  which is unassigned. In the complement event, there are less than  $t$  variables alive, and we may sample from a  $t$ -wise independent distribution to fool the remaining circuit. Overall the seed length is

$$\left( \frac{3 \ln(n)}{p'} \cdot \tilde{O}(\log^3(M/\varepsilon)) \right) + O(\log(1/\varepsilon) \cdot \log n) = \tilde{O}(\log^{d+1}(M/\varepsilon) \cdot \log n). \quad \blacktriangleleft$$
